Preface

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from virtually every medical journal published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis and
Metabolic Diseases
National Institutes of Health
Bethesda, Maryland 20014

Note

Journal names are abbreviated according to the system used by the National Library of Medicine for INDEX MEDICUS. Abbreviations used within the abstracts are published in each issue.

Acknowledgment

We wish to acknowledge gratefully the assistance of the National Library of Medicine in the preparation of this publication. The National Library of Medicine, through MEDLARS (Medical Literature Analysis and Retrieval System), is providing a recurring bibliography of gastroenterology-related citations which form a part of the literature included in this publication as citations or abstracts.

Use of funds for printing this publication
approved by the Director of the Bureau of
the Budget on August 26, 1965.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price a year in the United States, Canada, and Mexico, \$8.50; foreign \$10.75; and \$1.00 a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by Index Medicus. For journals not covered by Index Medicus, the abbreviations (with some modifications) found in World Medical Periodicals, 3rd Edition, are used.

- 6067 VITAMIN D MEDIATED SYNTHESIS OF RAPIDLY LABELED RNA FROM INTESTINAL MUCOSA. (E.) Norman, A. W. (U. California, Riverside). Biochem. Biophys. Res. Commun. 23(3):335-340, 1966.

Rachitic chicks were treated in vivo with 5,000 U of vitamin D₃ 0.5-5 hr. before intracardial inj. of 4-12 μ C of H³-uridine. Twenty min. after this inj. the chicks were sacrificed and RNA was isolated from the mucosa of the small intestine by the method of Hiatt or Scherrer and Darnell. One-half hr. after vitamin D₃ admin. there was a three-fold increase in the rate of RNA labeling. Five hr. after vitamin admin. there was only a modest increase in RNA labeling. There was a small increase in RNA labeling after 100 U of vitamin D₃ but no effect after 100 U of vitamin D₂. In similar experiments, prior admin. of actinomycin D or o,p'DDD (1-[2-chlorophenyl]-1-[4-chlorophenyl]-2,2-dichloroethane) inhibited the pulse labeling of RNA.

- 6068 CHOLECYSTOKININ AND PANCREOZYMIN, ONE SINGLE HORMONE? (E.) Jorpes, E. (Karolinska Inst., Stockholm, Sweden) and V. Mutt. Acta Physiol. Scand. 66(1-2):196-202, 1966.

Secretin, cholecystokinin, and pancreozymin are taken up by alginic acid from a dilute acetic acid extract of the heat-coagulated mucosa of hog duodenum and jejunum. After elution, they are precipitated with NaCl. From the salt cake secretin is taken up in methyl alcohol. The methanol-insoluble material had some cholecystokinetic activity. From this material cholecystokinin and pancreozymin were adsorbed on CMC cellulose and the active material was further chromatographed on TEAE cellulose. The product had 250 Ivy dog U of cholecystokinin per mg. Further purification (to 3,000-6,000 U/mg) was achieved by passage through a Sephadex G 50 column and subsequent chromatography on an Amberlite XE-64 column. Parallel with the rise in strength of cholecystokinin activity (assayed in the guinea pig) was an increase in pancreozymin activity (assayed in the cat). This observation strongly supports the assumption that both activities are exerted by one and the same substance. Both preparations are inactivated by dilute peroxide soln. and both are fully reactivated on subsequent reduction with cysteine hydrochloride.

- 6069 THE PHYSIOLOGIC DISPOSITION AND METABOLISM OF NOREPINEPHRINE IN IMMUNO-SYPATHECTOMIZED ANIMALS. (E.) Iversen, L. L. (NIH, Bethesda, Md.), J. Glowinski and J. Axelrod. J. Pharmacol. Exp. Ther. 151(2):273-284, 1966.

Immunosympathectomy was produced usually by a single s.c. inj. of sympathetic nerve growth factor-bovine antiserum when Sprague-Dawley rats and mice were 3 days old. Animals were used when they were 6-12 wk. old. After i.v. inj. of DL-7-H³-norepinephrine, uptake of drug in the salivary glands, liver, and intestine of treated rats was 30-60% of that found in tissues of controls. In general, the reduction in the accumulation of the norepinephrine in the tissues of treated animals paralleled the reduction in the endogenous catecholamine content of these tissues. A significant increase in serotonin was found in the intestine of treated mice. After i.v. inj. the tritiated norepinephrine was more rapidly metabolized in treated mice than in controls. All tissues of treated rats showed a relative increase in the accumulation of tritiated metabolites of norepinephrine, chiefly the O-methylated metabolite, normetanephrine. However, there was no change in catechol-O-methyl transferase activity in treated mouse tissues. In a study of monoamine oxidase activity, the only change noted was a decrease in the salivary glands of treated animals. Aromatic L-amino acid decarboxylase activity was decreased in treated heart, salivary glands and intestine, but not in liver or brain.

- 6070 SOME BIOCHEMICAL PROCESSES IN THE LARGE INTESTINE AND THE VITAL ACTIVITY OF THE NORMAL FLORA WITH DIFFERENT DIETS. (Rus.) Kuvaeva, I. B. (Inst. Nutr., Acad. Med. Sci. USSR, Moscow). Ernaehrungsforschung 10(2-3):159-166, 1965.

GENERAL

Dogs fed a sour milk-barley or a meat diet for 5 days showed marked changes within the large intestine. The sour milk-barley diet caused a decrease in pH from 6.5 to 4.2-4.5, with some decrease of ammonia compounds and organic acids. Phosphomonoesterase in the feces showed a 2-3-fold decrease, indicating changes in the biochemical processes within the lumen. Addition of pectin to this diet resulted in similar, but less marked changes. The meat diet resulted in an increase of pH to 7.0-7.5 with increase in ammonia compounds and organic acids; phosphatase in feces was also increased. The sour milk-barley diet resulted in a marked decrease in spore-bearing anaerobes and *Escherichia coli* as compared to the meat diet. *Lactobacillus acidophilus* content increased in some experiments when the sour milk-barley diet was changed to meat. A synthetic diet with the normal ratio of proteins, fats, and carbohydrates had the same effects as the protein-rich meat diet. Antibacterial drugs caused a marked excretion of enterokinase and phosphomonoesterase in the feces regardless of the diet given; pH of feces in both diets was 6.3-6.5. Feces with both diets contained an almost pure culture of yeast; with the sour milk-barley diet there were also large amounts of fungi (*Candida*). When thiamine was added to the diet, urinary excretion of the vitamin ceased while excretion in the feces was unchanged; with addition of lactose to the diet, there was a marked, sustained increase in fecal excretion of thiamine. Addition of lactose to the diet supplemented with pyridoxine caused an increase in the excretion of 4-pyridoxic acid in the urine 7-14 days after start of treatment. These studies indicate that the intestinal flora of the dogs could synthesize marked amounts of thiamine and pyridoxine.

- 6071 POSTNATAL CHANGES IN β -GALACTOSIDASE ACTIVITY IN THE JEJUNUM AND ILEUM OF MICE, RABBITS, AND GUINEA PIGS. (E.) Koldovský, O. (Inst. Physiol., Czech. Acad. Sci., Prague), A. Heringová, V. Jirsová, F. Chytil and J. Hošková. *Canad. J. Biochem.* 44(5):523-527, 1966.
Intestinal β -galactosidase activity was measured using 0.001 M o-nitrophenyl- β -D-galactoside as substrate. In mice, during the postnatal period, activity is always higher at pH 3.5 than at pH 5.5. The jejunum shows a steady decrease of activity whereas in the ileum the activity increases temporarily and later decreases. In the rabbit at pH 5.5 there is a steady decrease of β -galactosidase activity in the ileum and jejunum. However, at pH 3.5 there is a steady decrease in activity in jejunum only; in ileum there is first an increase and then a decrease. In newborn guinea pigs there is very little activity with only a small decrease during postnatal development. During postnatal development, the activity decreases less at pH 3.5 than at pH 5.5. Guinea pigs showed no substantial differences between jejunum and ileum in all the age groups studied.
- 6072 SURVIVABILITY OF INTESTINAL FLORA. (Ger.) Nikodemusz, I. (Inst. Natural Sci., Budapest, Hungary) and V. Hoch. *Zschr. Ges. Hyg.* 12(3):234-237, 1966.
- 6073 COLIFORM BACTERIA IN THE INTESTINE OF MICE. (E.) Mushin, R. (Rockefeller U., New York, N. Y.) and R. Dubos. *J. Exp. Med.* 123(4):657-663, 1966.
- 6074 ISOLATED FECAL MICROORGANISMS CAPABLE OF 7 α -DEHYDROXYLATING BILE ACIDS. (E.) Gustafsson, B. E. (Karolinska Inst., Stockholm, Sweden), T. Midtvedt and A. Norman. *J. Exp. Med.* 123(2):413-432, 1966.
- 6075 OBSERVATIONS ON SALIVA AGGLUTININS. (E.) Jakobowicz, R. (Queen Victoria Hosp., Melbourne, Australia), J. J. Graydon and R. T. Simmons. *Med. J. Aust.* 1(10):399-401, 1966.
- 6076 AUGMENTATION OF LYMPHATIC UPTAKE OF CHEMOTHERAPEUTIC AGENTS BY INDUCED HEPATIC OUTFLOW BLOCK. (E.) Grossi, C. E., L. M. Rousselot (170 W. 12th St., New York, N. Y.), E. M. Gonzalez, G. Doehner and A. J. Conte. *Arch. Surg. (Chicago)* 92(3):333-336, 1966.

- 6077 KINETICS AND DYNAMICS OF CELL POPULATION IN THE INTESTINAL EPITHELIUM. (Rus.) Alexsandrov, S. N. (Inst. Sci.-Res. Roent. Radiol., Min. Health USSR, Leningrad) and A. M. Kononenko. Ark. Anat. 48(12):9-15, 1965.

An attempt is made to identify a dynamic mechanism which conditions some regular laws of movement and shift of the epithelial cells in the small intestine. Since the intestinal epithelium represents a stationary system with components separated spatially and functionally (crypt-villus) it should possess some intrinsic forces which can account for the movement of the epithelial cells. The authors suggest that these forces are related to the pressure which is developed by the proliferative pool of the epithelium. On the basis of this assumption the following kinetic equation was developed: $\frac{dN}{dt} = [\beta(t) - K(N)]N$. $K(N) = 0$ at $N \leq N_0$; $K(N) > 0$ at

$N > N_0$ where N is a number of cells in a crypt; t = time; $\beta(t)$ = the coefficient of cell entry into the system due to reproduction; $K(N)$ = the coefficient of decrease of cells due to being forced out onto the villi; N_0 = minimum of cells in crypt under conditions where there is no pressure or movement of cells. Coefficient $K(N)$ which depends on N and is subjected to the conditions indicated above testifies to the existence of a negative feedback, that is, stabilization of the system. The supposed dynamic mechanism permits the conclusion to be drawn that the loss of cells by the intestinal epithelium was due not to the death of cells but to their being pushed off from the villi in the process of movement. Observations carried out on living mice proved that the movement of cells out of the intestinal epithelium is an active process.

- 6078 AN ELECTRON MICROSCOPIC STUDY OF DEVELOPING GALL BLADDER EPITHELIUM IN THE RABBIT. (E.) Hayward, A. F. (U. Glasgow, Scotland). J. Anat. 100(2):245-259, 1966.

Developing gallbladder epithelium was studied by phase contrast microscopy in rabbit fetuses and young sucklings, and comparison was made with gallbladder epithelium of adults. In adult rabbits, the gallbladder epithelium was composed of 2 types of cells: (1) a more common type associated with absorption, notably microvilli, limited pinocytosis, some lysosomes, an elaboration of the lateral cell membrane and intercellular spaces, and mitochondria concentrated in a subapical band; (2) a more infrequent type of dark, rod-shaped cell of unknown function, but which may be a dehydrated epithelial cell. Fetal epithelial cells lack the functional adult characteristics; their mitochondria are uniformly distributed and they display basal granules and apical apocrine bullae. Between day 24 and birth, or just after, epithelial cell damage and WBC infiltration occurs. Just before birth some epithelial cells are very large and pale with smooth outlines, others are more dense and display vigorous pinocytosis. Adult characteristics are acquired at or immediately after birth and pinocytosis subsides. It is believed that water resorption occurs before the functional changes which allow continuous passage of water into the circulation.

- 6079 THE INTRINSIC INNERVATION OF THE GALL BLADDER IN Macaca rhesus AND Cavia porcellus. (E.) Sutherland, S. D. (U. Manchester, England). J. Anat. 100(2):261-268, 1966.

The intrinsic innervation of the gallbladder was studied in monkeys (Macacus rhesus) and guinea pigs (Cavia porcellus) by neurohistological and histochemical methods. Cystic nerve plexuses in both animals may be subdivided into 5 subsidiary plexuses (subserosus, myentericus, muscularis profundus, entericus internus, and submucosus) comparable with those of the intestine. The equivalent of the myenteric (Auerbach) plexus is situated on the outer surface of the single muscular layer. The subdivision is artificial, however, for the plexuses are so interconnected that they form an extensive network throughout the whole thickness of the gallbladder wall. All the plexuses are ganglionated except the muscularis profundus, and the

CELLULAR STRUCTURE AND MORPHOLOGY

entericus internus in the guinea pig. The mucosa in the monkey remains rugose even after distention as it rests on a honeycomb reticular framework; this gives the plexus submucosus (Meissner) in this animal a characteristic whorled appearance.

- 6080 ARRANGEMENT OF THE RETICULAR FIBERS AND OTHER STRUCTURES IN THE VILLI OF THE SMALL INTESTINE OF DOGS. (E.) Naito, T. (Nagoya City U. Sch. Med., Japan). *Nagoya Med. J.* 11(2):61-74, 1965.

Histological studies (after staining with 8-azaguanine, Bielschowsky stain, Weigert stain, and hematoxylin eosin) of intestinal villi obtained from the duodenum, jejunum, and ileum of 9 dogs revealed a definite arrangement of reticular fibers. The reticular fibers attached to the basement membrane are arranged spirally or annularly around the surface of the lamina propria of the subepithelial portion of the villus, while the reticular fibers of smooth muscle fibers and blood vessels are thinner than the above but also arranged in a spiral or annular pattern. The reticular fibers of the stroma are arranged transversely to the longitudinal axis of the villus with intervals of 4-8 microns, giving a herring-bone effect when viewed in longitudinal section; this arrangement is also seen in the jejunum of man, but is not clearly evident in rats or rabbits. In the intestinal villus, blood vessels and smooth muscle fiber bundles run longitudinal to the axis of the villus, and the reticular fibers of the stroma connect these structures transversely helping them to move synchronously. The arrangement of smooth muscle fibers and reticular fibers of the arteriole and central lacteal indicate synchronous movement but different function. The reticular tissue of the lamina propria is believed to act as an extravascular pathway for suspensions and colloids.

- 6081 EFFECTS OF IONIZING RADIATION ON THE FINE STRUCTURE OF PANETH CELLS OF THE MOUSE. (E.) Hampton, J. C. (Northwestern U. Sch. Med. Dent., Chicago, Ill.). *Radiat. Res.* 28(1):71-83, 1966.

The effect of X-irradiation (3,000 r) on Paneth cells in 2-month-old Swiss mice was studied at intervals of 30 min. to 5 days after irradiation. Mice were given i.p. inj. of H^3 -labelled thymidine (750 μ c) 30 min. prior to sacrifice to permit electron microscopic autoradiography. Obvious changes were revealed by electron microscopy after 24 hr., when it was noticed that structures regarded as stages in Paneth cell granule synthesis no longer appeared. By days 3-5, progressive and significant decrease in the number of ribosomes both free in the cytoplasm and attached to endoplasmic membranes was observed along with other degenerative changes, but Paneth cells containing secretory granules were still present until day 5 in surviving animals. Paneth cells remained in the epithelium longer than villus epithelial cells after exposure to irradiation, and this was attributed to the apparent long turnover time and consequently longer life span of mature Paneth cells as compared to villus cells. The role of the undifferentiated cell and of the renewal time for a given cell population in intestinal radiation death is emphasized as an important cofactor with blockage of mitosis.

- 6082 THE DUODENAL PROGENITOR POPULATION. III. THE PROGENITOR CELL CYCLE OF PRINCIPAL, GOBLET AND PANETH CELLS. (E.) Thrasher, J. D. (U. Colorado Sch. Med., Denver) and R. C. Greulich. *J. Exp. Zool.* 161(1):9-19, 1966.

The duodenal progenitor population was studied with H^3 -thymidine and autoradiography in male Swiss albino mice to characterize the role that individual cell types (principal, goblet, and Paneth) have in the proliferative activity of the duodenal crypt of Lieberkühn. Incorporation of H^3 -thymidine into newly synthesized DNA of all 3 cell types was observed by 0.5 hr. after inj. Labeled principal and goblet cells were distributed from the first cell of the cryptal mouth to the last cell at the cryptal base. Most labeled cells were found in the central region of the crypt. Labeled Paneth cells were only found in the last 4 cells at the cryptal base. Analysis of the percentage of labeled metaphase and mitotic figures after H^3 -thymidine admin. showed that the progenitor cycle duration of principal and

CELLULAR STRUCTURE AND MORPHOLOGY

goblet cells was about 15 hr.; that of Paneth cell was approx. 80 hr. The mean S-phase duration was 7.4, 7.4, and 8.7 hr. for principal, goblet, and Paneth cells, resp. Thus the G₁ portion of the cell cycle was considerably longer for Paneth cells, while all phases of the progenitor cycle were of the same duration for principal and goblet cells. It thus appears that the 3 cell types comprise independent populations capable of self-renewal.

- 6083 THE ULTRASTRUCTURE OF THE GASTRIC MUCOSA IN NORMAL AND HYPOPHYSECTOMIZED RATS. (E.) Corpron, R. E. (U. Michigan Sch. Med., Ann Arbor). Am. J. Anat. 118(1):53-63, 1966.

Six intact Sprague-Dawley rats were pair-fed against hypophysectomized rats for 2-7 mo. following operation. The following cell types were distinguished in the neck of the fundic gland of the rat stomach: nondifferentiated cell, immature surface cell, mucous neck cell, and neck parietal cell. In the normal gland, these cell types resembled each other in the possession of a ground cytoplasm and nucleoplasm of low electron density, a poorly developed endoplasmic reticulum, few mitochondria and numerous free ribosomes. The most important structural difference between mucous neck and immature surface cells was the contrasting density of the secretory granules; both cell types differed from the nondifferentiated cell primarily in the presence of their characteristic secretory granules. The neck parietal cell appeared to be a developmental form between the immature surface cell and the mature parietal cell. No changes were seen in these cells after hypophysectomy. Hypophysectomy caused marked involutional changes in the chief cell which involved mainly the organelles most directly concerned with protein synthesis (ergastoplasm and Golgi apparatus). These effects were correlated with loss of basophilia and secretory granules and with the reduction in cell size and capacity to secrete pepsinogen. In contrast, the parietal cell, which is concerned with electrolyte transport, was affected much less.

- 6084 ON SPIRALITY IN THE INTESTINAL WALL. (E.) Elsen, J. (Northwestern U., Chicago, Ill.) and L. B. Arey. Am. J. Anat. 118(1):11-20, 1966.

It was not possible to demonstrate a significant spiral course of fibers within longitudinal muscle coats of the jejunum and ileum of the dog, cat, hog, or man by use of the method of stripping. The large intestine of the dog lacked spirality. The presence of taeniae in the hog and man, and the extremely thin layer of muscle between them, permitted only the demonstration of directly longitudinal muscle in taeniae. Bands of muscle stripped from circular coats of the small intestine of the dog and hog came off overwhelmingly in complete rings. Human intestine did not yield complete rings. Bands stripped from circular coats of the large intestine of the dog came off overwhelmingly as circles. The taeniae of the hog and man prevent obtaining complete strips. Stripping of the submucosal stratum of the small intestine of the dog and man, and of the large intestine of the dog, revealed a latticed tube.

- 6085 MICRORADIOGRAPHY OF THE RABBIT'S HEPATIC MICROCIRCULATION. THE SIMILARITY OF THE HEPATIC PORTAL AND PULMONARY ARTERIAL CIRCULATIONS. (E.) Reeves, J. T. (U. Kentucky Coll. Med., Lexington), J. E. Leathers and C. Boatright. Anat. Rec. 154(1):103-107, 1966.

Microradiographs were made of rabbit liver which was inj. with barium sulfate upon removal from the body. The microradiographs show that the hepatic arteries supply the richly anastomosing arterial plexus around the biliary ducts. This plexus supplies the portal veins directly and the peripheral hepatic sinusoids. Hepatic veins receive sinusoids at irregular angles and frequent intervals, whereas portal veins distribute flow through short right angle inlet venules spaced at greater intervals. Pulmonary arteries also distribute flow to capillaries through short right angle pre-capillaries and pulmonary veins receive capillary drainage at irregular angles and frequent intervals. The location of capillary beds of both

CELLULAR STRUCTURE AND MORPHOLOGY

liver and lung only 10-30 microns from inflow channels appears "ideally" suited for circulations of low vascular resistance. An analogy of lung and liver is presented.

- 6086 A COMPARISON OF THE EFFECTS OF X-IRRADIATION AND COLCHICINE ON THE INTESTINAL MUCOSA OF THE MOUSE. (E.) Hampton, J. C. (Northwestern U., Chicago, Ill.). Radiat. Res. 28(1):37-59, 1966.

Mice were inj. i.p. with 0.04 mg of colchicine once daily and sacrificed at intervals from 2 hr.-4 days. A second group was subjected only to X-irradiation (3 Krads) and were sacrificed at the same intervals. Light and electron microscopic examination of the intestinal epithelium showed that the characteristic loss of epithelium, the reduction in number and the abnormal appearance of mitochondria, and the depletion of ribosomes observed in the irradiated mice failed to develop in drug-treated animals. In addition, the extreme shortening of crypts and villi seen in irradiated animals also did not occur in colchicine-treated mice. These observations suggest that the effects produced by ionizing radiation cannot be attributed only to blockage of mitosis and interference with cell renewal.

- 6087 DEMONSTRATION OF THE FUNCTIONAL ANATOMY OF THE CANINE GASTRIC ANTRUM. II. OPERATIVE TECHNIQS NOT REQUIRING GASTROTOMY. (E.) More, R. E. (U. Amsterdam, The Netherlands) and P. J. Kloppe. Am. J. Surg. 111(1): 80-88, 1966.

Two methods are described for demonstrating the corpus-antrum boundary during laparotomy without performing a gastrotomy. One method consists of intragastric spraying of Congo red via the esophagus, followed by transillumination; when the gastric mucosa is sprayed with the dye, the antrum fails to take up the dye and is transilluminated, whereas the corpus is darkened. A spraying apparatus and a light are described. The other method was intragastric pH measurement using an esophagogastric pH glass electrode (also described). A sample pH tracing is included. Both methods satisfactorily demonstrated a similar corpus-antrum boundary. Other measuring technics were arteriography and gastric planar patterns. In 20 normal dogs, the av. relative planar area occupied by the antrum was $20 \pm 4.6\%$ (range 10-30%) of the total gastric area. The transillumination method was used to demonstrate the corpus-antrum boundary in ulcer patients; the results are not described.

- 6088 HISTOCHEMICAL STUDY ON THE PANETH CELL IN THE RAT. (E.) Riecken, E. O. (Postgrad. Med. Sch., London) and A. G. E. Pearse. Gut 7(1):86-93, 1966.

A histochemical study is presented of the Paneth cell from the small intestine of the hooded rat. These studies indicate that the main structural element of the membrane of the Paneth granules appears to be a carbohydrate-protein compound. The carbohydrate compound was a neutral mucopolysaccharide which was resistant to maltase digestion, thus excluding glycogen. Analysis of the protein fraction revealed reactive -NH₂ and -SH groups, tyrosine, arginine, and tryptophan. There appeared to be little lipid in the cells; there was some phospholipid. Zinc was found in the Paneth granules. Investigations of the enzymatic pattern of the Paneth cells showed a striking preponderance of the lysosomal enzymes, acid phosphatase and E 600-resistant esterase. There was little β -glucuronidase activity. The Paneth cell granules showed some association with monoamine oxidase and ubiquinones.

- 6089 MAST CELLS IN RAT GASTROINTESTINAL MUCOSA. I. EFFECTS OF FIXATION. (E.) Enerbäck, L. (U. Gothenburg, Sweden). Acta Path. Microbiol. Scand. 66(3):289-302, 1966.

A study is presented of the effects of different fixatives on the mast cells of various tissues of the gastrointestinal tract and of skin of the rat. In contrast to mast cells elsewhere, the intestinal mucosal mast cells are smaller, not so densely granulated and stain reddish rather than violet with toluidine blue at pH 4. The mucosal mast cells moreover lack the characteristic resistance to

CELLULAR STRUCTURE AND MORPHOLOGY

fixatives typical of other mast cells in the rat. In particular, intestinal mast cells cannot be demonstrated after fixation in 4% formaldehyde but their stainability with toluidine blue is well preserved after fixation in 0.4-0.8% formaldehyde soln. This fact, together with the behavior of intestinal mast cells after treatment with other fixatives, indicates that the granules of intestinal mast cells are more easily dissolved during the histological process than those of other mast cells. Based on these observations a fixative for mast cells has been formulated, containing 0.6% formaldehyde and 0.5% acetic acid. This fixative gives a good preservation of stainability with toluidine blue of both types of mast cell in the rat.

- 6090 MAST CELLS IN THE RAT GASTROINTESTINAL MUCOSA. II. DYE-BINDING AND METACHROMATIC PROPERTIES. (E.) Enerbäck, L. (U. Gothenburg, Sweden). Acta Path. Microbiol. Scand. 66(3):303-312, 1966.

In contrast to the mast cells of skin, intestinal mast cells have a lower affinity for thiazine dyes at pH 0.5. This was demonstrated by the lack of staining with toluidine blue of intestinal mast cells at pH 0.3 while dermal mast cells stained strongly. Similarly the staining of intestinal mast cells at pH 0.5 could be extinguished by decreasing the dye conc. or staining time whereas dermal mast cells showed little loss of staining intensity. On the other hand, basic copper phthalocyanine dyes (such as Astra blue) seem to have stronger affinity for intestinal than for dermal mast cells. Thus intestinal mast cells stained strongly with Astra blue at pH 0.3 in an Astra blue-safranin sequence. After exposure to this same sequence, dermal mast cells stained partly blue and partly red, the proportion of cells staining blue being dependent on the type of fixative used.

- 6091 MAST CELLS IN RAT GASTROINTESTINAL MUCOSA. III. REACTIVITY TOWARDS COMPOUND 48/80. (E.) Enerbäck, L. (U. Gothenburg, Sweden). Acta Path. Microbiol. Scand. 66(3):313-322, 1966.

The mast cells which occur in large numbers in the gastrointestinal mucosa have been reported to differ from other mast cells in the rat, both histochemically and morphologically. Intravenous inj. of histamine liberator Compound 48/80 (0.2 and 0.8 mg/100 g) into rats resulted in degranulation of the mast cells in mesentery, tongue and skin. Mast cells in duodenal mucosa, on the other hand, appeared unaffected. After i.p. inj. of 48/80 in increasing doses twice daily for 5 days, there resulted an almost complete disappearance of mast cells from all the tissues examined except gastrointestinal mucosa. After treatment, counts in different areas of the intestinal mucosa revealed an almost two-fold increase in mast cells.

ABSORPTION

- 6097 REGULATION OF AMINO ACIDS IN THE INTESTINE. (Rus.) Klemina, E. A. (Acad. Med. Sci. USSR, Moscow), O. A. Shishova and V. I. Kasatochkin. Vop. Pitan. 24(6):31-34, 1965.

Rats kept on a histidine-deficient diet for a prolonged period of time showed no conversion of endogenous histidine in the intestine. The velocity of the transport of labeled lysine remained stable, and intake during the stationary stage of the process was not dependent on conc. Endogenous nitrogen was not a determining factor for the velocity of intake during the stationary period. The velocity constants for the intake of single amino acids from a mixture depended somewhat upon the initial conc. On the basis of their intake velocity constants, the amino acids could be arranged in the following order: arginine > leucine plus isoleucine > lysine > tyrosine > threonine > glutamic acid > alanine > histidine > tryptophan. Those amino acids which are present in larger amounts in dietary proteins are absorbed with greater velocity than those present in smaller amounts.

- 6098 THE EFFECT OF SUBTOTAL GASTRIC RESECTION ON COPPER METABOLISM IN THE ORGANISM OF DOGS. (Rus.) Fuzailov, Iu. M. (Andizhan Inst. Med., USSR). Vop. Pitan. 24(6):53-57, 1965.

In 5 of 6 dogs with subtotal (Billroth II) gastrectomy, the level of copper in the blood fell approx. by one-third of the preoperative values during a period of 1.5-4.5 mo. after surgery. After 4-5 mo. the blood copper level in the internal organs was markedly reduced. Compared to controls, there was less copper in the mucous membranes of the stomach and intestine; this is apparently due to less absorption in the operated dogs. The phenomenon of "copper hunger" in the organism may become one of the causes giving rise to the development of gastrogenic anemia.

- 6099 ON THE NATURE OF THE "NON-SATURABLE" MIGRATION OF AMINO ACIDS INTO EHRlich CELLS AND INTO RAT JEJUNUM. (E.) Christensen, H. N. (U. Michigan, Ann Arbor) and M. Liang. Biochim. Biophys. Acta 112(3):524-531, 1966.

Segments of rat jejunum were suspended in Krebs-Ringer bicarbonate, in which labeled amino acids replaced NaCl isoosmotically. Levels of 75 and 150 mM were used to saturate ordinary transport systems. For L-phenylalanine Q_{10} values of 2.5 and 4.8 were obtained in 2 different experiments of 5 min. duration, for the range 37°-27°C; for α -aminoisobutyric acid a typical value of 2.4 was observed. Thus, as with the Ehrlich cell, uptake of amino acids at high levels by rat intestinal segments also showed high temperature sensitivities.

- 6100 A STUDY OF ABSORPTION OF VITAMIN B₁₂ USING A WHOLE-BODY SPECTROMETER. (E.) Tappin, J. W. (Middlesex Hosp. Sch. Med., London, W. 1), I. A. Rahman and K. Rogers. Brit. J. Radiol. 39(460):295-301, 1966.

The absorption of Co⁵⁸-labeled vitamin B₁₂ was determined in various groups by use of a whole-body spectrometer; these results were compared with those obtained by the Schilling test. The test had to be performed in different individuals since the Schilling test involves the inj. of a large amount of non-radioactive vitamin. The correlation between the two tests is good. With the use of the spectrometer, after 5-7 days 3 malabsorption patients absorbed an estimated 3.9-7.2% of the initial dose; four absorbed 10.4-14.8%; the remainder absorbed 20.4, 33.6, and 45.1%. Among controls 13 absorbed over 50% of the dose; 12 absorbed 30-40% of the dose; two absorbed 21% and 26% of the dose. The malabsorption group excreted from 0.5% to 8.4% of the dose, as determined by the Schilling test.

- 6101 THE EXOCRINE PANCREAS AND IRON ABSORPTION. (E.) Biggs, J. C. (St. Vincent's Hosp., Sydney, Australia) and A. E. Davis. Aust. Ann. Med. 15(1):36-39, 1966.

Uptake of Fe⁵⁹-labeled FeSO₄ (25 μ g) in segments of rat small intestine isolated

ABSORPTION

by balloons *in situ* av. 51% (range, 36-81%). When sheep pancreatic juice (100 mg) was added with the iron, mean uptake was significantly reduced to 16% (range, 5-37%). This inhibitory effect appears to be more marked at pH 7 than pH 5 or pH 2. Under similar conditions, addition of gastric juice or trypsin showed no significant inhibitory effect. After dialysis of the pancreatic juice, an effect on iron uptake was produced by both the dialysate and diffusate; this suggests that the factor involved is capable of partial diffusion through dialysis tubing, or alternatively, that more than one factor is involved.

- 6102 METABOLISM AND SODIUM TRANSPORT IN THE ISOLATED RAT INTESTINE. (E.)
Esposito, G. (Inst. Gen. Physiol., Milan, Italy), A. Faelli and V. Capraro.
Nature (London) 210(5033):307-308, 1966.

Everted jejunal sacs from male Wistar rats were incubated in an organ bath in which the mucosal surface was bathed in medium containing 1.39, 2.78 or 13.9 mmoles of glucose per liter. When the results of all experiments were put together, regression lines were calculated which show a correlation between sodium transport and oxygen consumption, as well as between sodium transport and lactic acid production. In order to compare the total available energy with the sodium transport, the total amount of ATP was calculated. The regression line again showed a statistically significant relationship to sodium transport. The ratio $\Delta\text{ATP}/\Delta\text{sodium}$ was nearly unity.

- 6103 MECHANISM OF COMBINED GLUCOSE, GLYCINE AND SODIUM CHLORIDE ABSORPTION IN THE SMALL BOWEL OF DOGS. (Rus.) Faitelberg, R. O. (Mechnikov U., Odessa, USSR) and Z. N. Alekseeva. *Fiziol. Zhur. SSSR Sechenov*. 52(1):91-98, 1966.

The extent of absorption of 5 or 10% glucose, 0.03 M glycine and 1 or 2% NaCl from isolated intestine loops of dogs depended not only on the conc. but on whether the compounds were admin. alone or in combination. Glucose absorption was increased when admin. together with NaCl or glycine; glycine absorption was depressed when given with glucose or 2% NaCl while it was stimulated by 1% NaCl. NaCl absorption was stimulated by glucose admin., and to a lesser extent, by glycine. Administration of KCl instead of NaCl caused a slight increase in glucose absorption; LiCl had no effect. The frequency of contraction of the villi was increased by absorption of the following: water, 75%; glucose, 22%, glycine, 42%; and NaCl by 2-4%. Contraction was stopped by topical application of 0.02% monoiodoacetic acid. Absorption is connected with respiration. The respiration of mucous membrane was increased by absorption of the following: water, 33-44%; glucose, 25-35%; glycine, 23-69%; and NaCl, 16-87%. Respiration was less markedly affected by mixtures than by the pure compounds. There was a relationship between the absorption of oxygen, the frequency of contraction of the villi and the intensity of absorption. In the preparation of synthetic food mixtures, it is necessary to add 1% NaCl to stimulate absorption.

- 6104 CERTAIN REGULARITIES OF GLUCOSE ABSORPTION FROM THE SMALL INTESTINE. (Rus.)
Amirov, N. Sh. (Inst. Norm. Path. Physiol., USSR Acad. Med. Sci., Moscow).
Biull. Eksp. Biol. Med. 61(1):28-32, 1966.

In dogs, regional arterial trunks of portions of the small intestine were perfused with homologous blood. Absorption of glucose (10% soln.) from the lumen of the intestine was directly related to the vol. of blood flow. Not all glucose which left the lumen of the intestine entered the blood; the difference was called the sugar deficit. This deficit ranged usually between 5-25%, and sometimes reached 35-40%. The sugar deficit generally was inversely proportional to the blood vol. in the regional vessels. Absorption of sugar into blood and the sugar deficit were also linked to blood pressure. When perfusion was initiated at a low arterial pressure, sugar intake into the blood was low and the sugar deficit high. These experiments indicate that the level of oxygenation of the blood plays an essential role in the process of absorption.

ABSORPTION

- 6105 **ROLE OF THE CARBOXYL GROUP IN INTESTINAL AMINO ACID TRANSPORT.** (E.) Spencer, R. P. (Yale U. Sch. Med., New Haven, Conn.), K. R. Brody and F. E. Vishno. *Biochim. Biophys. Acta* 117(2):410-415, 1966.

No transport against a conc. gradient occurred using the hamster everted small intestine in vitro if the COOH group of an α -amino acid was replaced by CH₂OH, CH₃, CO·C₆H₅, or CO·NHOH. Transport apparently occurred when the replacing group was CO·NH₂. Apparently in these cases deamination or transamination (producing the free amino acid) probably preceded transintestinal transport of the compound. 2-C¹⁴-Glycine methyl ester hydrochloride, purified to free it of glycine, was not transported by everted intestinal sacs from hamster, rat or chinchilla. There was thus no appreciable esterase activity under these conditions. Three phosphonic acid analogs (R-CHNH₂·PO₃H₂) did not inhibit amino acid movement (suggesting -PO₃H₂ cannot replace -COOH). A sulfonic acid analog (R-CHNH₂·SO₃H) was not completely stable under these conditions; it was not transported, and was not a transport inhibitor. Aminoiminomethane sulfinic acid also did not inhibit transport. Carboxylic acids alone, and amines plus carboxylic acids, were not effective inhibitors of amino acid transport. An -SO₃⁻ or a second -COO⁻ group on the amino acid converted a transported molecule into one that was not transported and also did not inhibit amino acid movement.

- 6106 **THE UPTAKE OF ATROPINE AND RELATED DRUGS BY INTESTINAL SMOOTH MUSCLE OF THE GUINEA-PIG IN RELATION TO ACETYLCHOLINE RECEPTORS.** (E.) Paton, W. D. M. (U. Oxford, England) and H. P. Rang. *Proc. Roy. Soc. London* 163B:1-44, 1966.

In a study of the properties of acetylcholine receptors in intestinal smooth muscle, measurements were made of the uptake of tritium-labeled atropine and methylatropinium, and of C¹⁴-labeled methylfurmethide by the longitudinal muscle of guinea pig small intestine in vitro. Substantial amounts of atropine were taken up from very dilute soln., a clearance of 160 ml/g tissue (wet wt.) being achieved at the lowest conc. tested (1.5×10^{-10} M). Analysis of the curve relating atropine uptake at equilibrium to the bath conc., explored over a conc. range 1.5×10^{-10} to 2.5×10^{-3} M, enabled 3 components to be distinguished: (1) A binding site with a capacity of 180 picamoles/g, and equilibrium constant 1.1×10^{-9} M. (2) A binding site of capacity about 1,000 picamoles/g and equilibrium constant about 5×10^{-7} M. (3) A compartment with a clearance of 4.7 ml/g (non-saturable). Methylatropinium was taken up in smaller amounts than atropine, and analysis of the uptake curve showed a binding site of capacity about 90 picamoles/g with an equilibrium constant of 6.5×10^{-10} M, an ill-defined series of binding sites with much higher equilibrium constants, and a constant clearance of about 0.4 ml/g. The equilibrium constant for blockade of acetylcholine receptors by methylatropinium was 4.7×10^{-10} M. Studies with various metabolic inhibitors suggested that no metabolic energy was required for the accumulation of atropine, and by dialysis experiments, the atropine taken up was shown to be bound to homogenized tissue. A theoretical study, using an analog computer, was made of the kinetic properties of 3 passive binding systems, in order to see whether the observed kinetic behavior could be simulated. A system of 4 binding sites in series, with only one communicating directly with the surrounding medium, could show these kinetic properties, and the outermost binding site could still show the kinetic behavior of receptors. Methylfurmethide was taken up very slowly (more than 24 hr. to reach equilibrium), reaching a clearance of about 5 ml/g after 6 hr. This uptake was unaffected by atropine in a conc. sufficient to block 80% of acetylcholine receptors, but was blocked by depolarization in high potassium soln.

- 6107 **INCREASED ACTIVE TRANSPORT OF GLUCOSE THROUGH THE INTESTINE DURING PREGNANCY.** (E.) Larralde, J. (U. Santiago, Compostela, Spain), P. Fernandez-Otero and M. Gonzalez. *Nature (London)* 209(5030):1356-1357, 1966.

ABSORPTION

Wistar rats which were pregnant 12-15 days were perfused with soln. of 300, 150, 75 and 20 mM D-glucose at 12 cm of water for 30-min. periods. The Sols y Ponz technic of successive absorptions in vivo was used. Compared to a similar, non-pregnant group of rats, the pregnant rats showed highly significant increases in absorption at all conc., ranging from 21% for 300 mM to 40% for 20 mM.

- 6108 ACTIVE TRANSPORT OF IRON BY INTESTINE: EFFECT OF ERYTHROPOIESIS STIMULATED BY PHENYLHYDRAZINE. (E.) Manis, J. (Columbia U. Coll. Phys. Surg., New York, N. Y.) and D. Schachter. Nature (London) 209(5030):1356, 1966.

Following admin. of phenylhydrazine (100 mg/kg, s.c.) to rats (80-140 g), the initial mean hematocrit, 42%, decreased to 29% at 3 days and returned to the control value at 7 days. At this time 2 consecutive everted sacs were prepared from the proximal portion of the small intestine and incubated in a bath which contained both Fe⁵⁹-labeled and unlabeled FeSO₄. After 2.5 hr. phenylhydrazine treatment increased net transfer of iron (estimated chemically) to the serosal surface by 19.7% and 54.7%, resp., in the proximal and adjacent distal segments. Final Fe⁵⁹ conc. ratios serosal/mucosal were increased 24.4% and 54.8%, resp. Sacs prepared from intestine more than 10 cm distal from the pylorus showed no clear effect of prior phenylhydrazine treatment.

- 6109 THE DISTRIBUTION OF DISACCHARIDASE ACTIVITIES IN THE VILLI AND CRYPTS OF THE SMALL-INTESTINAL MUCOSA. (E.) Dahlqvist, A. (U. Lund, Sweden) and C. Nordström. Biochim. Biophys. Acta 113(3):624-626, 1966.

A technic is presented for the study of disaccharidase activities in the villi and crypts of small intestine mucosa. A block of ice on a cryostat is trimmed so that its surface is parallel to the cutting edge. A piece of jejunum is affixed to the block with the villi pointing upwards from the block. Starting at the top, every third section (each 10 microns) is used for histochemical and histologic study, while the intervening 2 are homogenized and analyzed for disaccharidase activity by an ultramicro method (Messer and Dahlqvist). In one experiment, the first 30 sections contained only villi, the next 10 both villi (basal parts) and crypts, the last 30 sections contained only crypts. Disaccharidase activity (maltase, invertase, isomaltase, trehalase and lactase) was present in all the sections which contained villi. The specific activity of the disaccharidases was highest in the apical half of the villi, but the highest levels were not always in the topmost sections. In the basal parts of the villi the specific activities always decreased, and in the crypts they were essentially zero in all experiments.

- 6110 THE EFFECT OF MEMBRANE FIXED CHARGES ON DIFFUSION POTENTIALS AND STREAMING POTENTIALS. (E.) Diamond, J. M. (Harvard Med. Sch., Boston, Mass.) and S. C. Harrison. J. Physiol. (London) 183(1):37-57, 1966.

The electrical potential difference between the mucosal and serosal surface of the in vitro everted rabbit gallbladder preparation was always found to be zero when the same bathing soln. was present simultaneously on the mucosal and serosal surfaces, regardless of the composition of the soln. This indicated that the mucosal and serosal cell membranes had the same relative permeability coefficients. Osmotic water flow produced streaming potentials of up to 20 millivolts. Calcium ion (5 mM relative to 0.25 mM) reduced (1) streaming potentials by 40%, (2) sodium chloride diffusion potentials by 62% and (3) potassium diffusion potentials by 43%. The aqueous channels through which water and electrolytes traversed the gallbladder cell membrane contained negative fixed charges which were blocked by calcium. The author suggested that the physiological significance of the charges might be to reduce chloride permeability and to increase the effectiveness of the gallbladder in concentrating bile.

- 6111 NON-LINEAR OSMOSIS. (E.) Diamond, J. M. (Harvard Med. Sch., Boston, Mass.). J. Physiol. (London) 183(1):58-82, 1966.

ABSORPTION

The relationship between osmotic gradient and rate of osmotic water flow was measured in an *in vitro* everted rabbit gallbladder preparation. Streaming potentials were directly proportional to gravimetrically measured water fluxes. There was no consistent relationship between water permeability and either the direction or rate of water flow. Resistance to water flow increased linearly with osmolarity over a range of 186-825 milliosmols, but was the same when the gallbladder separated any two bathing soln. with the same av. osmolarity, regardless of the magnitude of the gradient. Experimental measurements of water permeability as a function of osmolarity indicated that non-linear osmosis in the rabbit gallbladder was due to a decrease in water permeability with increasing osmolarity. The results suggested that the aqueous channels in the cell membrane behaved as osmometers, which shrank in conc. soln. of impermeant molecules and thus increased membrane resistance to water flow.

- 6112 A RAPID METHOD FOR DETERMINING VOLTAGE-CONCENTRATION RELATIONS ACROSS MEMBRANES. (E.) Diamond, J. M. (Harvard Med. Sch., Boston, Mass.). J. Physiol. (London) 183(1):83-100, 1966.

Changes in the conc. of bathing soln. of an *in vitro* rabbit gallbladder preparation were made instantaneously (by placing the gallbladder into a fresh soln.) and the potential difference was measured as a function of time, while the conc. at the membrane continuously changed due to diffusion through an unstirred layer. The potential difference was converted to membrane conc. from preconstructed time-conc. equations. This method produced non-linear voltage-conc. curves in good agreement with those obtained by conventional methods but required much less time and experimental manipulation. The thickness of the unstirred layers in the rabbit gallbladder were measured and found to have a negligible effect upon the steady state streaming potentials and the sodium chloride diffusion potentials. The changes of permeability with osmolarity found in the rabbit gallbladder must be complete within a fraction of a second, in agreement with the interpretation that they represent swelling and shrinking of the cell membrane itself.

- 6113 SODIUM-GLUCOSE INTERACTIONS IN THE GOLDFISH INTESTINE. (E.) Smith, M. W. (A.R.C. Inst. Anim. Physiol., Babraham, Cambridge, England). J. Physiol. (London) 182(3):559-573, 1966.

Everted goldfish intestine sacs transferred glucose and water from the mucosal to the serosal surface; the total transfer was greater in the anterior intestine than in the intestinal bulb or rectum. Transmural potentials were highest in the anterior intestine and rectum and the total potential was partly dependent on the presence of glucose. The glucose-evoked potential was directly but non-linearly related to the sodium conc. This potential increased rapidly over a temperature range of 5-15°C and more slowly from 15-30°C and was inhibited by phlorhizin. Steady state potentials first increased, then decreased as sodium concentration was reduced; they increased with temperature, with a greater rate of increase when glucose was present. Below 15°C the glucose-independent potential was higher, and above 15°C lower, than the steady-state potential recorded with glucose present.

- 6114 INFLUENCE OF TEMPERATURE ACCLIMATIZATION ON SODIUM-GLUCOSE INTERACTIONS IN THE GOLDFISH INTESTINE. (E.) Smith, M. W. (A.R.C. Inst. Anim. Physiol., Babraham, Cambridge, England). J. Physiol. (London) 182(3):574-590, 1966.

Transmural potentials across everted goldfish intestine sacs depended on the acclimatization temperature of the fish. The transmural and glucose-evoked potentials were lower in fish kept previously at a high temperature (30°C). The steady transmural potential increased, then decreased as the sodium conc. was reduced, while the glucose-evoked potential fell as soon as the sodium conc. was reduced below 140 mM; these changes were more dependent on external sodium conc. in high temperature acclimated fish. Temperature acclimatization had no effect on the glucose-evoked potential. The inhibitory effect of glucose on the steady potential depended on previous acclimatization temperature. It is concluded that sodium moves across the

ABSORPTION

luminal mucosal membrane attached to a carrier which could exist in two forms. Changes in this carrier stabilized sodium transport at different acclimatization temperatures.

- 6115 THE EFFECT OF INHIBITORS ON INTESTINAL TRANSFER OF GLUCOSE AND FLUID.
(E.) Detheridge, J. F. (U. Sheffield, England), J. Matthews and D. H. Smyth. J. Physiol. (London) 183(2):369-377, 1966.

Fluid and glucose transfer were studied in the *in vitro* inverted gut sac of the first, third, and fifth segments of the rat small intestine (divided into 5 segments). Fluid transfer was greatest in sac 3 (mid-jejunum to ileum). In the presence of glucose, phlorhizin (5×10^{-4} M), 2,4-dinitrophenol (2×10^{-4} M), fluoride (5×10^{-3} M), fluoroacetate (10^{-2} M), and anaerobic conditions reduced fluid transfer in all 3 sacs. In the absence of glucose, control values were less than those with glucose present, and all inhibitors tested reduced fluid transfer in all sacs. Phlorhizin and fluoride strongly inhibited glucose-dependent fluid transfer, while fluoroacetate had little effect. Glucose transfer was depressed in sacs 1 and 3 by all inhibitors; in sac 5 (ileum), only phlorhizin and 2,4-dinitrophenol had a small depressant effect. The two-stage transfer of glucose was discussed as an explanation of the results.

- 6116 RECENT DATA ON THE EFFECT OF PHLORHIZIN ON THE INTESTINAL ABSORPTION OF AMINO ACIDS. (Fr.) Pérès, G. (U. Lyon Fac. Sci., France) and M. Buclon. Arch. Sci. Physiol. (Paris) 20(1):1-8, 1966.

The authors summarize their previously reported data on the effect of phlorhizin on the intestinal absorption of amino acids. The intestinal absorption of glycine was decreased in fish (*Tinca tinca*, *Scorpaena porcus*, and *Scyliorhinus canicula*) and rats by 17-25% and 28%, resp., in the presence of phlorhizin. In subsequent experiments with L- and D-glutamic acid and L- and D-alanine, phlorhizin (0.02 M soln.) inhibited intestinal absorption of these amino acids by approx. 30%. Significant inhibition of glycine absorption was seen with conc. of phlorhizin as low as 2×10^{-3} M. Rutoside, a glucoside of similar molecular wt. and stereochemical structure, had no inhibitory effect on glycine absorption, indicating a specific effect of phlorhizin. Results suggest that active transport plays an important role in the intestinal absorption of amino acids.

- 6117 INTESTINAL ABSORPTION OF VITAMIN B₁₂ IN RATS SUBJECTED TO GASTRIC RESECTION OR DIVERSION. (Fr.) Lambert, R. (Nat. Inst. Health, Lyon, France), G. Vouillon, F. Martin, J. Amiel and J. Site. C. R. Soc. Biol. (Paris) 159(11):2212-2217, 1965.

Intestinal absorption and fecal elimination of vitamin B₁₂ following the admin. of 15 mg of the vitamin (Co⁵⁸-labelled) was studied in intact Wistar rats (Group 1), in rats subjected to total gastrectomy with subsequent esophagojejunostomy (Group 2), in rats subjected to end-to-side esophagojejunostomy with lateral exclusion of the stomach (Group 3), and in rats subjected to the same treatment as Group 3 as well as admin. of tetracycline to the drinking water (Group 4). Absorption of vitamin B₁₂ was practically nil in rats of Group 2 (0.004 mg/g of rat wt.) as compared to Group 1 (0.025 mg/g); absorption was markedly decreased in animals of Group 3 (0.015 mg/g) and Group 4 (0.012 mg/g) but differences between the 2 groups were not significant. Semi-logarithmic curves of fecal elimination of vitamin B₁₂ were exponential for operated rats (Groups 2, 3, and 4) but not for intact rats. Total fecal elimination of vitamin B₁₂ in Groups 1, 2, 3, and 4 was 53.9%, 92.5%, 72.7%, and 79%, resp. Various interpretations of results are included.

- 6118 EFFECT OF ORAL DESFERRIOXAMINE ON THE INTESTINAL ABSORPTION OF Fe⁵⁹ AND UTILIZATION OF THE ABSORBED ISOTOPE. INTERACTION WITH ERYTHROPOIETIN. (Fr.) Aschkenasy, A. (Dept. Hemat., C.N.R.S., Montrouge, Seine, France). C. R. Soc. Biol. (Paris) 159(11):2154-2158, 1965.

ABSORPTION

Iron absorption and utilization was studied in male Sherman rats treated with Fe^{59} ($0.2 \mu\text{C}$ in 1 ml of iron ammonia sulfate soln. ($10 \mu\text{g/ml}$) admin. by stomach tube) after feeding of normal diets (Group 1), non-protein diets (Group 2), or normal diet for 3 days after 7 wk. of complete nitrogen deprivation (Group 3); desferrioxamine ($25 \text{ mg}/100 \text{ g p.o.}$) was admin. by stomach tube to some of the animals of each group; rats of Group 2 received inj. of plasma rich in erythropoietin (2 ml/day). In Group 1, the admin. of desferrioxamine reduced intestinal absorption of ionized Fe^{59} , inhibited the utilization of the isotope in erythropoiesis, and increased urinary excretion of the absorbed Fe^{59} . In Group 2, inj. of erythropoietin had no effect on Fe^{59} absorption but inhibited the decreased utilization of Fe^{59} in erythropoiesis (characteristic of the initial period of nonprotein diet), consequently increasing the utilization of absorbed Fe^{59} ; desferrioxamine had no effect on absorption of Fe^{59} , increased its urinary excretion, and inhibited the effect of erythropoietin on Fe^{59} utilization; after 7 days, Fe^{59} conc. in the blood was 1.45% with erythropoietin and desferrioxamine as compared to 2.47% with erythropoietin alone; the effect of desferrioxamine was on Fe^{59} utilization and not on stable tissue deposits of the isotope. In Group 3, desferrioxamine slightly increased Fe^{59} absorption, inhibited the utilization of Fe^{59} in erythropoiesis, and increased urinary excretion of the isotope.

- 6119 FOCAL DISTURBANCES OF ELECTRICAL ACTIVITY OF THE INTESTINE IN RELATION TO ACTIVE TRANSFER DURING ABSORPTION. STUDIES IN ANESTHETIZED RATS. (Fr.) Rougureau, A. (U. Tours Sch. Med. Pharm., France) and J. Thouvenot. C. R. Soc. Biol. (Paris) 159(10):2020-2023, 1965.

Electrical activity was studied in duodenal and intestinal loops of anesthetized rats during absorption. Double unipolar derivation was possible with electrodes placed at 2 points with a distance of 3 to 5 mm between them. During active absorption, the usual rhythm of smooth muscle contraction was interrupted after 4-12 (av. 7.5) sec. and a series of oscillations of small amplitude and increased frequency (activity "A") were observed. Activity "A" appeared after a latency period of 200 sec. (av.) during the absorption of glucose, galactose, ribose, and mannose alone or in association with ATP. The sudden appearance of this activity seems to correspond to the cessation of ionic and electric interaction at the level of the muscular layer.

- 6120 FAT ABSORPTION IN PATIENTS WITH CHAGAS' DISEASE AND ITS CORRELATION WITH THE ORAL GLUCOSE TOLERANCE TEST. (Por.) Bühler Vieira, C. (U. Sao Paulo Fac. Med., Brazil) and U. G. Meneghelli. Hospital (Rio) 69(3):575-582, 1966.

Intestinal fat absorption after loading (0.5 g/kg of butter according to a technic described by Osmon) and fecal fat content were studied in 30 patients (15 men and 15 women) with chronic Chagas' disease (positive Machado-Guerreiro test). Patients were either asymptomatic or had minor symptoms; no pathological dilatations of the gastrointestinal tract were present. No significant difference in max. values of serum fat turbidity were observed between the Chagas' group and controls (medical students). In 3 patients, max. turbidity values were less than the minimum values in controls. Fecal fat content was normal in the 25 patients investigated by this method. Blood glucose curves were abnormally high in 11 of 29 (37.9%) patients, among whom were the 3 patients with deficient intestinal absorption of fat. Results could indicate vagus inhibition due to Chagas' lesions of the intramural plexuses.

- 6121 THE EFFECT OF CHOLESTYRAMINE ON FECAL EXCRETION OF INGESTED RADIOIODINATED LIPIDS. (E.) Danhof, I. E. (U. Texas Southwest. Sch. Med., Dallas). Am. J. Clin. Nutr. 18(5):343-349, 1966.

The absorption of neutral fat (^{131}I -labelled triolein) and fatty acid (^{131}I -labelled oleic acid) was studied in 15 normal male subjects (age 20-26 yr.) fed self-

ABSORPTION

selected diets containing 55-95 g of fat daily to which cholestyramine was added in doses of 12, 24, or 36 g/day. Side effects at these dosage levels were minimal and included transient initial nausea, epigastric fullness, abdominal distention, increased flatulence, and constipation; no significant diarrhea, systemic symptoms, or changes in hematograms or urinalyses were observed. Significant lowering of serum cholesterol values occurred at each of the 3 dosage levels, but no enhancement of this reduction was seen after ingestion of more than 12 g of cholestyramine per day. No significant impairment in the absorption of triolein or oleic acid occurred at dosage levels of 12 g/day. Some impairment in neutral fat absorption, but essentially normal oleic acid absorption, was observed with doses of 24 g/day. Significant impairment of both triolein and oleic acid absorption occurred following the ingestion of 36 g of cholestyramine per day.

- 6122 THE EFFECT OF ORAL NEOMYCIN ON THE RAT INTESTINE. (E.) Robinson, J. W. L. (U. Lausanne, Switzerland), J. A. Antonioli and J. Fasel. Gastroenterologia (Basel) 105(3):129-138, 1966.

Groups of adult Wistar rats received 1 or 3 or 7 daily doses of neomycin sulfate (0.5 g in 1 ml of water, intragastrically). At varying times after the last dose, the ileum was removed and studies were performed on rings. When the ileal rings were incubated with C^{14} -L-phenylalanine, there was increased amino acid uptake after 1 or 3 doses which was most pronounced after 7 doses of neomycin. When the rings were incubated with glucose, there was little change in metabolic activity. No marked histologic changes were noted in intestine from treated rats. Although the rats showed evidence of diarrhea, the fecal fat was greatly reduced after neomycin treatment. This lends support to the theory that most fecal fat in neomycin-treated rats originates in colonic bacteria.

- 6123 INHIBITION OF INTESTINAL ABSORPTION BY DIFFERENT SAMPLES OF CETRIMIDE AND THE HOMOLOGOUS ALKYL SERIES C10-C20. (E.) Hart, S. L. (Guy's Hosp. Sch. Med., London, S.E. 1) and J. A. Nissim. J. Pharm. Pharmacol. 18(4): 228-235, 1966.

The effect of different batches of cetrimide (cetyltrimethylammonium bromide) and of homologous compounds of the same alkyl series on absorption was tested by in vivo intraluminal perfusion of the entire intestine of mice and guinea pigs, and by perfusion of the proximal 60 cm of the intestine of the rat. In mice, at a conc. of 10^{-3} , the original preparation (Sample A) had a marked inhibitory effect on the absorption of glucose, but only a moderate inhibitory effect on sodium butyrate and DL-methionine absorption. A later sample (Sample B) in CBA mice showed only moderate inhibition of absorption of the 3 compounds; the C3H mice Sample B showed somewhat marked inhibition of glucose absorption. In similar tests with rats, Sample B resulted in very little inhibition of absorption of butyrate and methionine. In the guinea pig Sample B led to a moderate inhibition of butyrate and methionine, but caused an increase in glucose conc. in the lumen of the intestine. When the C10 to C20 homologs were tested, generally they were not as active as Sample A.

- 6124 EFFECTS OF WHOLE-BODY IRRADIATION ON THE TRANSFER CAPACITY OF RAT SMALL INTESTINE. (E.) Perris, A. D. (U. Sheffield, England), E. L. Jervis and D. H. Smyth. Radiat. Res. 28(1):13-29, 1966.

Transfer of glucose and fluid was studied in everted sacs of small intestine removed from rats at various periods of time after whole-body radiation. Sham-irradiated rats were given the reduced amount of food consumed by irradiated rats. A combined section of the jejunum and ileum was divided into 5 parts, and the third (middle) and fifth (lowest) segments were used. Some effects were indirect, due to reduced presentation of food to the epithelial cells; some effects were direct and due to irradiation changes in the cells. Both direct and indirect effects reduced the transfer capacity of the intestine. In the third segment the capacity for

ABSORPTION

transfer of both glucose and fluid was reduced, whereas in the fifth segment the capacity for fluid transfer was reduced. The time course of the indirect effects was the same in the third and fifth sacs; these effects were best seen on day 2 after irradiation. The direct effects varied in the third and fifth segments. In the third segment the greatest effects appeared on day 3, whereas in the fifth segment the greater effects appeared on day 2.

- 6125 A TIME SEQUENCE STUDY OF FAT ABSORPTION IN THE RAT JEJUNUM. (E.) Jersild, R. A., Jr. (Indiana U. Med. Ctr., Indianapolis). Am. J. Anat. 118(1):135-141, 1966.

Physiologic fatty chyme, prepared from fat-fed donor rats, was inj. into ligated segments of the upper jejunum of fasting recipient animals. In some experiments tritiated oleic acid was added to the chyme for light and electron microscopic radioautography. When tissue was removed at different intervals from 1-30 min., results indicate that fat is absorbed and transported through the epithelium very rapidly. Within 1 min., fat droplets can be seen in the endoplasmic reticulum and the Golgi apparatus. Fat is shown to be absorbed during, not prior to, experimentation by the radioautographic identification of labeling in the vicinity of fat droplets throughout the cell. Accumulation of label within the Golgi apparatus within 1-2 min. may be indicative of a rate-limiting step in absorption. The phenomena noted within the Golgi apparatus may be responsible in part for the cellular saturation with fat which is evident in 8-10 min. The sequential pattern can be followed in cells along the entire length of the villus.

- 6126 THE PASSAGE OF DRUGS ACROSS THE RAT INTESTINE IN VITRO. (E.) Misra, A. L. (CIBA Ltd., Basel, Switzerland), A. Hunger and H. Keberle. J. Pharm. Pharmacol. 18(4):246-251, 1966.

The passage of drugs from the mucosal to the serosal side of rat intestine was determined using the in vitro intestine perfusion technic of Smyth and Taylor and the everted sac technic of Crane and Wilson. Ferrioxamine-B hydrochloride and 3 other ferrioxamines were not significantly absorbed. Utilizing C^{14} -labeled compounds, it was seen that glutethimide was more rapidly absorbed than thalidomide. Val⁵-angiotensin-Asp- β -amide was broken down rapidly and appeared as amino acids in the serosal fluid. Salicyclic acid and aniline were found in the serosal fluid but phenol red was not absorbed to any great extent. Despite the lack of functional capillary networks in these in vitro preparations, it is felt that these technics can supply useful information on the intestinal permeability characteristics of newly developed drugs.

- 6127 THE CONSEQUENCES OF INGESTION BY MAN OF REAL AND SIMULATED FALLOUT. (E.) LeRoy, G. V. (U. Chicago, Ill.), J. H. Rust and R. J. Hasterlik. Health Phys. 12(4):449-473, 1966.

The behavior of real and simulated fallout following ingestion was studied in 102 volunteers using the whole-body gamma spectrometer. In 10 subjects who ingested samples of typical local fallout, the av. absorbed radioactivity was 3%. Two absorbed almost none and only 4 absorbed more than 3%. In 27 subjects, on the av. about one-half of insoluble particulate matter ingested was excreted during the first 2 days. In all but 3 of 17 subjects 99.9% was gone by day 7. Simulants (microspheres or particles of calcined masses) of fallout labeled with Sr^{85} , Cs^{134} , or Ba^{133} were fed to 43 subjects and soln. of $Sr^{85}Cl_2$ or $Cs^{134}Cl$ were fed to 22. The rate of elimination of strontium and cesium was the same whether given in soln. or whether it was absorbed from the simulant. On the av., about 17% of the strontium was absorbed. Of the amount absorbed, about 60% was retained at the end of the first wk. and about 16% at the end of 1 yr. When $Sr^{85}Cl_2$ was fed, the fraction absorbed ranged from 0.08-0.34. In 12 subjects the biological half-time for elimination of Cs^{134} was 91 ± 18 days. When $Cs^{134}Cl$ was fed about 90% was absorbed. Using $BaO + Ba^{133}O$ as a distant simulant av. absorption was 6% in 8 subjects

ABSORPTION

(range 1-15%). There was no correlation between the biological availability of the simulants and leachability or solubility as measured by soak tests in 0.1 N HCl and 0.1 N NaOH.

- 6128 STUDIES ON ABSORPTION OF PROTEOLYTIC ENZYMES (PRONASE-P) IN THE INTESTINE. ON TRANSFERENCE OF PRONASE-P IN EVERTED SACS OF INTESTINE OF THE RABBIT. (Jap.) Sugie, I. (Nagoya City U. Sch. Med., Japan), R. Sugino, S. Miyachi and H. Nitta. Nippon Seirigaku Zasshi (J. Physiol. Soc. Jap.) 28(1): 18-26, 1966.

Proteolytic activity of Pronase-P was measured on a heated fibrin plate to which ϵ -aminocaproic acid was added. There was a linear relationship between proteolytic activity and the extent of the lysed area on the plate. Using the rabbit everted intestine sac preparation, transference of proteolytic activity from the mucosal to the serosal side was proportional to the conc. of Pronase-P employed. In this preparation, there was a greater transference of Pronase-P than of trypsin or α -chymotrypsin. The transference of α -chymotrypsin was enhanced by pre-incubation with Pronase-P. Treatment of the intestine with ouabain (which disturbs the active transport of inorganic ions) had no effect on transport of Pronase-P. Treatment with potassium cyanate interfered with the transfer of Pronase-P.

- 6129 SPECIES DIFFERENCES IN THE RESPONSE OF AMINO ACID TRANSPORT TO OUABAIN AND A SODIUM-FREE MEDIUM. (E.) Binder, H. J. (Yale U. Sch. Med., New Haven, Conn.), M. Boyer, H. M. Spiro and R. P. Spencer. Comp. Biochem. Physiol. 18(1):83-89, 1966.

Active transport of C^{14} -labeled lysine and methionine was studied in 3 rodent species by use of everted sacs of small intestine made according to the method of Wilson and Wiseman. The transport of L-methionine and L-lysine was not inhibited in the hamster and mouse in the presence of 10^{-4} ouabain, an inhibitor of the sodium-dependent adenosinetriphosphatase. Lysine and methionine transport in the guinea pig was inhibited following the addition of ouabain. There was complete inhibition of transport of both amino acids in hamster and guinea pig intestine in a medium in which sodium was replaced by choline. In the mouse, however, there was minimal movement of both compounds in the absence of sodium.

- 6130 THE DISTRIBUTION OF DIPEPTIDASE ACTIVITY IN THE SMALL INTESTINE OF THE SHEEP (*Ovis aries*). (E.) Symons, L. E. A. (McMaster Lab., C.S.I.R.O., Glebe, New South Wales, Australia) and W. O. Jones. Comp. Biochem. Physiol. 18(1):71-82, 1966.

Distribution of the dipeptidase activity in the small intestine of sheep was determined using L-leucylglycine, glycyl-L-leucine, and glycyl-L-tyrosine. In the mucosa, the activity per mg of extracted protein rose progressively from duodenum to jejunum to mid-ileum. The activity in the distal ileum was slightly lower than in the mid-ileum but was higher than in the proximal intestine. There was no significant difference between the dry wt. of the mucosa from these 4 regions of the intestine. The water content of the mucosa of the ileum was higher than that of duodenum and jejunum. The luminal contents relative to the mucosa showed low dipeptidase activity; this finding is consistent with the hypothesis that dipeptides are absorbed before hydrolysis. The distribution of dipeptidase activity in the sheep small intestine was found to be similar to that for rat and pig; however, limited studies indicated some differences in the characteristics of individual enzymes.

- 6131 THE ABSORPTION FUNCTION OF THE INTESTINE FOLLOWING INTAKE OF MINERAL WATER. (Rus.) Vasilenko, Iu. K. (Piatigorsk Inst. Balneother., USSR). Vop. Kurort. Fizioter. 31(1):37-40, 1966.

- 6132 THE EFFECT OF VAGOTOMY ON GASTRIN-STIMULATED GASTRIC-ACID SECRETION IN MAN. (E.) Barabas, A. P. (Hammersmith Hosp., London, W. 12), R. A. Payne, I. D. A. Johnston and G. P. Burns. Lancet 1(7429):118-119, 1966. The max. acid secretion responses to histamine (0.04 mg/kg/hr. for 2 hr.) and graded doses of gastrin (2-6 μ g/kg) were studied in 4 normal subjects and in 13 patients with duodenal ulcer; 9 of the ulcer patients were tested before and after vagotomy with pyloroplasty. The gastrin used was a commercial mixture (Leo 64121) of Gastrins I and II, and caused no side effects. Completeness of vagotomy was demonstrated by the insulin test in 9 of the ulcer patients. The max. acid response occurred regularly in the second 60 min. after gastrin or histamine admin. There was no increase in acid response in the third hr., even at the highest gastrin dose; no inhibition of secretion was seen. The max. gastrin and histamine responses were closely related. Mean preoperative acid secretion at the times of max. histamine and gastrin response in the 9 ulcer patients was 44.1 and 41.1 mEq/hr., resp., while mean postoperative secretion was 16.7 and 27.3 mEq/hr., resp., indicating that vagotomy decreased the max. histamine and gastrin responses by 62.7% and 32.9%, resp. The ulcer patients had higher acid responses to both gastrin and histamine than the normal subjects, but the patterns of response were similar.
- 6133 STIMULATION OF RNA SYNTHESIS IN THE SALIVARY GLAND BY ISOPROTERENOL. (E.) Barka, T. (Mt. Sinai Hosp., New York, N. Y.). Exp. Cell Res. 41(3):573-579, 1966. Isoproterenol stimulated the incorporation of H^3 -uridine and H^3 -orotic acid into total and nuclear RNA fractions of the rat submaxillary gland. The max. stimulation in the nuclear fraction occurred 12-18 hr. after the admin. of the drug and it was sensitive to actinomycin D. The same dose of actinomycin D (250 mg/kg) which suppressed nuclear RNA formation was without effect on the incorporation of C^{14} -algal protein hydrolysate into the proteins of salivary gland and pilocarpine-stimulated saliva.
- 6134 ROLE OF VAGUS AND SPLANCHNIC NERVES IN TRANSMISSION OF HYPOTHALAMIC INFLUENCES ON GASTRIC SECRETION. (Rus.) Kosenko, A. F. (Shevchenko U., Kiev, USSR). Fiziol. Zhur. SSSR Sechenov. 52(2):179-183, 1966. Gastric secretion was stimulated in 4 Pavlov pouch dogs by feeding a meat meal. Gastric juice was collected hourly for 6 hr. Parts of the brain were stimulated electrically for 3 min. out of every 15 min. for 6 hr. by means of implanted electrodes. When the electrodes were placed in the region of the hypothalamus, there was no effect on the amount or dynamics of gastric secretion after meat feeding. Stimulation of the anterior part of the hypothalamus caused a slight increase in secretion for 1-2 hr. after feeding. Stimulation of the posterior hypothalamus caused increased gastric secretion after 3-6 hr.; acidity remained unchanged or was increased. Stimulation of the anterior and central portions of the hypothalamus mostly changed the first phase; stimulation of the posterior portion changed the second phase of gastric secretion. Bilateral vagotomy decreased gastric secretion in the first phase but had no effect on that of the second phase. There was a decrease in both acidity of gastric secretion and digestive strength; the latter was especially noted during the first 2 hr. Stimulation of the central portion of the hypothalamus of vagotomized dogs caused even greater decreases in secretion, acidity and digestive strength in both phases of gastric secretion. Stimulation of the posterior portion of the hypothalamus caused an increase in gastric secretion during the last 2-3 hr. of the experiment; total vol. of secretion during the 6-hr. period was also increased. Thus, stimulation of the posterior hypothalamus caused increased secretion in the second phase, and had no effect on the first phase. Additional splanchnicotomy caused a decrease in gastric juice acidity during hr. 1-3. Stimulation of the central hypothalamus increased secretion

SECRETION

throughout the experiment; acidity was also increased. Stimulation of the posterior hypothalamus of these dogs caused even greater increases in gastric secretion; acidity was more significantly increased in the second part of the experiment.

- 6135 EFFECTS OF CONCURRENT MOTOR ACTIVITY ON THE UNCONDITIONED SALIVARY REFLEX. (E.) Feather, B. W. (Duke U. Med. Ctr., Durham, N. C.) and D. T. Wells. *Psychophysiology* 2(4):338-343, 1966.

Twenty-four subjects, after citric acid stimulus (applied to the left lateral margin of the posterior half of the tongue), were told to perform swallowing movement during the first or second 30-second period or during the entire 60-second period after stimulation. Saliva was collected by a parotid capsule and measured by a sensitive liquid displacement sialometer. Motor activity was monitored by an electromyogram. There was a significantly greater amount of saliva secreted during periods of motor activity, regardless of time since stimulation. Voluntary inhibition of swallowing immediately after acid stimulation resulted in significantly longer and more variable salivary unconditioned reflex latencies.

- 6136 THE EFFECTS OF A GASTRIC INHIBITORY SUBSTANCE ON GASTRIC SECRETION IN THE PYLORUS LIGATED RAT. (E.) Semb, L. S. (Ulleval Hosp., Oslo, Norway). *Acta Physiol. Scand.* 66(3):374-382, 1966.

An extract was prepared from juice secreted by vagally denervated isolated pouches of the gastric antrum in the dog, by dialyzing against water followed by lyophilization. This gastric inhibitory substance was assayed in pylorus-ligated male, Long-Evans rats. When compared to 3 groups of controls (untreated, i.v. saline or i.p. saline), the gastric inhibitory substance lowered significantly the basal or spontaneous output of acid, but did not alter the basal output of pepsin significantly. When the gastric inhibitory substance was inj. into rats which were stimulated by gastrin, there was a highly significant decrease in the output of both acid and pepsin.

- 6137 THE EFFECT OF RESTRAINT ON THE CONTENT OF ACID POLYSACCHARIDES OF GLANDULAR GASTRIC WALL IN RAT. (E.) Häkkinen, I. (U. Turku, Finland), K. Hartiala and H. Lang. *Acta Physiol. Scand.* 66(3):333-336, 1966.

Female Wistar rats (180-200 g) which were fasted for 12 hr. were subjected to restraint for from 5-48 hr. Lesions were found only in the glandular stomach. Most ulcers developed in the 24-hr. group; none were found after 5-20 hr. Small petechiae or superficial erosions were found after 5-20 hr. The aminosugar content of acid polysaccharides in the gastric wall of the glandular stomach was increased slightly in the 'pre-ulcerous' groups and fell sharply to below control values in the ulcer groups. Fractionation of polysaccharides from the ulcer groups showed that the fractions believed to contain connective tissue polysaccharides (chondroitin sulfuric acid and hyaluronic acid) and one of the fractions containing epithelial mucopolysaccharides fell significantly.

- 6138 GASTRIC ANTISECRETORY AND OTHER PHARMACOLOGIC STUDIES ON 2,2'-BIPYRIDINE. (E.) Bass, P. (Parke, Davis & Co., Ann Arbor, Mich.), A. Purdon, M. A. Patterson and D. E. Butler. *J. Pharmacol. Exp. Ther.* 152(1):104-115, 1966.

The title compound (CI-588) decreased secretion vol. and hydrogen ion and pepsin outputs in the 4-hr. pylorus-ligated rat and reduced food-stimulated secretion vol. and hydrogen ion outputs in dogs with innervated gastric pouches. At the doses tested, CI-588 had no significant effect on insulin- or histamine-stimulated secretion in dogs. CI-588 reduced stress-induced gastric lesions in rats, and antagonized histamine-induced gastric lesions in guinea pigs, but had minimal effect against polymyxin B-induced gastric lesions in rats. CI-588 had no effect on acetylcholine- and dimethylphenylpiperazinium iodide-induced blood pressure changes in the dog or on methacholine-induced chromodacryorrhea in the rat. It showed no mydriatic activity in the rat. It is concluded that the gastric antisecretory

SECRETION

activity of CI-588 is due to an action on mechanisms other than those of the cholinergic system. Reserpine antagonism of the antisecretory activity of CI-588 in rats was partially reversed by di-3,4-dihydroxyphenylalanine and 5-hydroxytryptophan; the epinephrine and norepinephrine effects on blood pressure in dogs were partially antagonized by high doses of CI-588. This suggests that the sympathetic and possibly the serotonergic systems are involved in the activity of CI-588.

- 6139 PROELASTASE AND ELASTASE IN THE PANCREATIC JUICE OF THE RAT UNDER VARIOUS SECRETORY CONDITIONS. (Ger.) Schoenemann, J. (U. Rostock, Germany) and K. Diwok. Zschr. Ges. Inn. Med. 21(4):113-116, 1966.

Pancreatic elastase and proelastase excretion was measured in rats with pancreatic fistulas, after treatment with secretin alone or together with Jestryl, pilocarpine, methacholine (Mecholyl), or pancreozymin. Max. stimulation of pancreatic proelastase production (up to a 10-fold increase over control levels) was seen with pancreozymin and methacholine (in decreasing order); the increase seen with pilocarpine was significantly less (about 5-fold). In these animals, the increase in proelastase secretion was greatest 15 min. after stimulation; the secretion rate fell steeply after that time. Proelastase secretion fell slightly after secretin admin.; addition of Jestryl slightly stimulated secretion, to about control levels. Even with max. stimulation of proelastase secretion (with pancreozymin), only traces of elastase were present in the pancreatic juice. This pattern resembled that seen with other pancreatic proteases, such as trypsin and chymotrypsin.

- 6140 THE COMPOSITION OF HUMAN SALIVA SECRETED IN RESPONSE TO A GUSTATORY STIMULUS AND TO PILOCARPINE. (E.) Dawes, C. (U. Manitoba, Winnipeg, Canada). J. Physiol. (London) 183(2):360-368, 1966.

Parotid saliva was collected from 6 subjects and submandibular saliva was obtained from 1 subject during stimulation by either sucking sour lemon drops or by pilocarpine (12-15 mg p.o.). The protein conc. of submandibular saliva remained constant during a 1-hr. stimulation with candy, but rose to a plateau in the first 20 min. in parotid saliva. Only slight changes in inorganic ions and no change in protein composition of saliva were seen over this 1-hr. period. At a given flow rate, the sodium conc. was slightly lower and potassium conc. was over 20% lower after pilocarpine than candy stimulation. There was no difference in inorganic phosphate conc. in saliva after the 2 stimuli, but calcium conc. was 50-100% higher and protein content was 100-400% higher (in 6 of 7 subjects) in the pilocarpine-stimulated parotid saliva. It is concluded that pilocarpine is not a suitable physiological stimulus for salivary secretion.

- 6141 ALDOSTERONE EFFECT ON CANINE GASTRIC JUICE. (E.) Gilder, H. (U. California Med. Ctr., San Francisco) and F. G. Moody. Proc. Soc. Exp. Biol. Med. 121(3):913-918, 1966.

Aldosterone acetate (0.5-0.1 mg i.v.) did not alter either the basal gastric secretion of adrenalectomized or intact Heidenhain pouch dogs or the gastric secretion stimulated by histamine phosphate (3-5 µg/kg/min. i.v. or 0.5 mg/10 min. s.c.) or food of intact pouch dogs. Adrenalectomy did not change basal gastric secretion but did reduce histamine- or food-stimulated secretion. Pepsin output was reduced by adrenalectomy in basal and food-stimulated tests.

- 6142 ON THE BIOLOGICAL ASSAY OF SECRETIN. THE REFERENCE STANDARD. (E.) Jorpes, J. E. (Karolinska Inst., Stockholm, Sweden) and V. Mutt. Acta Physiol. Scand. 66(3):316-325, 1966.

The authors review various methods for the biological assay of secretin in dogs, cats, and rats. A detailed description is presented of the cat assay method devised by Mutt and Soderberg in which cats are maintained in good condition under Placidyl anesthesia for 4-5 days and which permits some 50 tests to be performed in the same animal. Techniques are also described for rat assay tests according to Love, Heatley, Svatos and Jelinek, Vaille, Debray, and others. The interrelationship

SECRETION

between the different units for the expression of secretin activity is discussed. Various attempts to select a reference standard, and the difficulties encountered, are reviewed. The authors recommend frequent controls of the strength of the standard with any of the known technics.

- 6143 LOCALIZATION BY IMMUNOFLOUORESCENCE OF AMYLASE, TRYPSINOGEN AND CHYMOTRYPSINOGEN IN THE ACINAR CELLS OF THE PIG PANCREAS. (E.) Yasuda, K. (Keio U., Tokyo) and A. H. Coons. J. Histochem. Cytochem. 14(4):303-313, 1966.

An immunofluorescence technic (using antisera prepared in rabbits against commercial crystalline enzyme preparations) has been used in the localization of various enzymes and enzyme precursors in the pig and beef pancreas. Porcine α -amylase was abundant in almost every acinar cell and was distributed as fine granular material in the basal portion of the cell or in some of the zymogen granules in the juxta-nuclear region; the enzyme was also visible in the Golgi zone. Bovine chymotrypsinogen and trypsinogen were present in the presumably less mature zymogen granules in the cytoplasm around the nucleus, but the granules near the lumen failed to react with the antisera probably because they were hidden by superficial material. Anti-amylase serum specificity was high, while that of anti-trypsinogen and anti-chymotrypsinogen was lower because of cross reactions with each other. Acinar cells were virtually all similar in both pig and beef pancreas, indicating functional similarity to the extent of these observations.

- 6144 VITAMIN B₁₂ DEFICIENCY FOLLOWING PARTIAL GASTRECTOMY. (E.) Weir, D. G. (Fed. Dublin Voluntary Hosp., Ireland), I. J. Temperley and P. B. B. Gatenby. Irish J. Med. Sci. 6(483):97-102, 1966.

Serum vitamin B₁₂ estimations were conducted in 61 of 79 patients who had had a partial gastrectomy (60 Polya; 19 Billroth I) within the last 15 yr.; significantly lower mean serum levels (334.8 μ g/ml) were observed in comparison to those (mean of 472 μ g/ml) of 118 normal controls; values were below 200 μ g/ml in 18 (29.5%) and below 150 μ g/ml in 7 (11.5%) patients. Megaloblastic changes were present in 4 of 69 (5.8%) patients, 3 of whom had abnormally low vitamin B₁₂ absorption. Both serum vitamin B₁₂ levels and absorption levels showed a significant decrease as the years progressed. Results indicate latent progressive vitamin B₁₂ deficiency after partial gastrectomy which in 10 yr. or more may become manifest clinically as megaloblastic anemia. The cause of this deficiency may be lack of intrinsic factor due to progressive degeneration in the mucosa of the gastric remnant.

- 6145 CHANGES IN AMYLASE LEVELS OF THORACIC DUCT LYMPH AFTER ADMINISTRATION OF SECRETIN AND THEIR RELATIONSHIP TO AGE. (Cz.) Barto $\check{s}$, V., V. Brzek and J. Groh. Sborn. Ved. Prac. Lek. Fak. Karlov. Univ. 8(4):467-471, 1965.

Among 18 men with no apparent gastrointestinal disease, 9 were 40 yr. old or less (av. 35.6 ± 2.9 yr.) and 9 were over 60 yr. old (av. 68 ± 4.7 yr.). Lymph from the thoracic duct and venous blood were taken prior to, and 1, 2, 3, and 4 hr. following the i.v. admin. of 75 units of secretin. Amylase conc. in the lymph and in the serum were determined by Teller's method. Lymph amylase levels were significantly higher and more prolonged in the older patients. No significant difference in serum amylase levels were noted in the 2 age groups. Functional differences may reflect senile changes of the pancreas or pancreatic ducts (i.e., sclerosis, hyperplasia, or metaplasia).

- 6146 GASTRIC BIOPSY AND SECRETION. RESULTS OF A CONTROLLED STUDY OF 20 PATIENTS AFTER FIVE YEARS. (Cz.) Kocianova, J., Z. Maratka, J. Kudrman and J. Kruml. Cesk. Gastroent. Vyz. 20(1):1-8, 1966.

Gastric biopsies were performed and gastric secretion was studied in 86 patients with various gastric diseases. The correlation between biopsy findings and max.

SECRETION

HCl conc. and HCl output after admin. of histamine and insulin was investigated. The values of these indicators were found to decrease with increasing inflammatory changes. Results indicate that the estimation of max. HCl conc. after histamine stimulation is an easy and suitable method for the biochemical diagnosis of gastritis, and is particularly useful in advanced inflammation where correlation between secretion and the degree of inflammation is close. Estimation of the HCl output after histamine stimulation is more difficult and therefore less suitable for the biochemical diagnosis of gastritis. However, it is more accurate in assessing the volume of secretion. A total of 20 patients were followed for 5 yr. by these methods (i.e., repeated biopsies and secretion studies). No differences were found in patients with normal findings and atrophic gastritis. Superficial gastritis, however, was usually improved in patients with a normal secretory function but progressed towards atrophy in patients with a low secretory capacity.

- 6147 EFFECT OF INTERMITTENT LUMINOUS STIMULATION OF THE RETINA ON GASTRIC SECRETION. (It.) Nicosia, A. (U. Messina, Italy). Ann. Ottal. 91(11): 915-922, 1965.

The effect of intermittent light stimulation (80 lux; 1 every second for 15 min.) of the retina on gastric secretion was studied in 12 subjects (8 women and 4 men; age 18-59 yr.) with no clinical or radiological evidence of gastrointestinal disturbance. After fasting from the night before, patients were kept in the dark for 30 min. before beginning light treatment; gastric secretion was collected with an Einhorn catheter 15, 30, and 60 min. after stimulation; gastric acidity was determined by the Töpfer-Linossier method. An increase in the quantity of gastric juice secreted and in total acid content was observed. In 8 subjects, the increase was evident 15 min. after the last stimulation and a peak was reached at 30 min.; a peak occurred after 15 min. in 3 and after 60 min. in 1 subject. A discussion of the role of the anterior hypothalamus in gastric secretion is included.

- 6148 SOME QUATERNARY, NON-ANTICHOLINERGIC COMPOUNDS WITH AN INHIBITORY ACTION ON "SHAY RATS". (E.) Antonsen, S. (Alfred Benzon Ltd., Copenhagen, Denmark). Acta Pharmacol. (Kobenhavn) 23(2-3):154-164, 1965.

The actions of 3 quaternary, non-anticholinergic compounds were studied in Shay rats and were compared with that of an anticholinergic drug, Metropin ([diphenylmethoxy]-ethyl-methyl-diethylammonium iodide). The test compounds, benzyl-tri-n-amylium ammonium iodide, benzyl-(β -propoxyethyl) ammonium iodide, and benzyl-(β -butoxyethyl) ammonium bromide had an inhibitory action on the secretion of gastric juice as well as on ulceration, either given i.p. or introduced directly into the gastrointestinal canal. An inhibitory action was also obtained in vagotomized and in histamine-treated Shay rats. The 3 test compounds had no spasmolytic actions or any effect on the autonomic nervous system that can explain the inhibitory action in Shay rats.

- 6149 GASTRIC SECRETION OF RATS AFTER TEST MEALS. (E.) Antonsen, S. (Alfred Benzon Ltd., Copenhagen, Denmark). Acta Pharmacol. (Kobenhavn) 23(2-3): 165-178, 1965.

The test method (technic of Thornton and Clifton) involves the intragastric admin. of a liquid meal (15% soln. of sucrose) to normal female rats, with complete aspiration 45 min. later. With the test meal some phenol red is also admin. in order to determine what vol. of fluid has passed out of the stomach. Histamine (1.5 mg i.p.) was admin. to all rats. The histamine liberator, compound 48/80 (0.5 mg s.c.), admin. 15 to 120 min. before the test meal markedly reduced HCl secretion. Caffeine (5-10 mg i.p., 20-40 mg p.o.) also inhibited acid secretion. The response to the 40 mg dose of caffeine may have been due to general toxicity since 2 animals died the following night. Metropin ([diphenylmethoxy]-ethyl-methyl-diethylammonium iodine also inhibited acid secretion. An analog, α -methyl-metropin had a greater inhibiting action on acid secretion than Metropin. The antihistamine compound antazoline was found to stimulate gastric secretion.

SECRETION

- 6150 APPLICATION OF TEST MEAL METHOD FOR INVESTIGATING THE EFFECT OF SOME QUATERNARY NON-ANTICHOLINERGIC SUBSTANCES ON THE RAT STOMACH. (E.) Antonsen, S. (Alfred Benzon Ltd., Copenhagen, Denmark). Acta Pharmacol. (Kobenhavn) 23(2-3):179-188, 1965.

Drugs tested were benzyl tri-n-amyllumonium iodide (U247-42), benzyl tri(β -propoxyethyl)ammonium iodide (U247-51), and benzyl tri(β -butoxyethyl)ammonium bromide (U247-73); their effects were compared to those of the anticholinergic agent (di-phenylmethoxy)ethyl-methyl-diethylammonium iodide (Metropin). In the liquid test meal method of Thornton and Clifton (in rats treated at various times with histamine, 1.5 mg s.c.), both U247-42 and U247-51 greatly inhibited gastric acid secretion after p.o. or s.c. admin. (1.25 mg s.c. had about the same effect as 5 mg p.o.). These agents were unsuitable for s.c. admin., as they caused irritation and pain at the inj. site; they also had an adrenaline-like pressor effect after i.v. admin. to anesthetized animals. After s.c. inj., both agents also caused marked fluid retention in the stomach; this effect was also seen after p.o. admin. of U247-51, but not of U247-42. After i.p. admin. (1.25 mg), U247-51 caused max. inhibition of acid secretion after 3 hr., but also had a significant effect after 1 or 5 hr. Non-acid secretion was briefly stimulated. U247-73 had a stronger inhibitory effect on acid secretion than U247-51 after i.p. admin. (each 1 mg), but U247-73 caused no gastric fluid retention, and in fact slightly increased the rate of passage into the small intestine. After i.p. admin., Metropin caused max. inhibition of acid secretion at a slightly later time than did U247-51 and had the same brief, strong retention effect, but did not increase non-acid secretion. Its effect on acid secretion was slight and transient after p.o. admin. Metropin did not affect the action of p.o. admin. U247-51. It is suggested that these agents have a sympathomimetic action.

- 6151 RAPID RELEASE OF THE ZYMOGEN GRANULE PROTEIN BY OSMIUM TETROXIDE AND ITS RETENTION DURING FIXATION BY GLUTARALDEHYDE. (E.) Amsterdam, A. (Hebrew U., Jerusalem, Israel) and M. Schramm. J. Cell Biol. 29(2):199-207, 1966.

Zymogen granules were isolated from the pancreas and parotid glands of the rat. Various conc. of osmium tetroxide led to variable degrees of clearing of the suspension. Protein determinations showed that this fixative caused rapid release of most of the soluble protein of the granule during fixation in buffered isotonic sucrose. Such granules when examined in the electron microscope after shadow casting appeared quite flat, indicating that most of the content had indeed been removed. In contrast, zymogen granules fixed by glutaraldehyde and shadow cast essentially retained the spherical shape and the protein contents.

- 6152 GASTRIC SECRETION MEDIATED BY EXTRAVAGAL NEURAL INFLUENCES. (E.) Hockman, C. H. (Med. Coll. Virginia, Richmond) and E. C. Hoff. M.C.V./Q. 1(1):28-29, 1965.

Adult cats, anesthetized with ether and immobilized with a curarimimetic agent (Flaxedil), were used in a study of the effects of electrical stimulation of cerebral loci on gastric secretion. Stimulation of mesencephalic and diencephalic areas increased both the vol. and acidity of samples collected hourly. Section of the spinal cord at the level of the second cervical vertebra abolished this secretion; however, subsequent stimulation in the lateral funiculus of the distal end of the severed cord elicited the response. These studies provide further evidence for the extravagal mediation of gastric secretion.

- 6153 FLUID PRODUCED BY THE GASTRIC MUCOSA DURING DAMAGE BY ACETIC AND SALICYLIC ACIDS. (E.) Davenport, H. W. (U. Michigan, Ann Arbor). Gastroenterology 50(4):487-499, 1966.

The sources and causes of the large output of fluid from the oxyntic gland area of the gastric mucosa frequently seen after damage by acetic and salicylic acids were sought in 4 healthy, unanesthetized dogs provided with separated, vagally denervated

SECRETION

pouches of this area of the stomach. Plasma output was measured using Cr⁵¹-albumin, and interstitial fluid output was estimated from glucose and sodium outputs. There was a greater amount of plasma put out after damage than before damage but this accounted for no more than 33% of the total vol. Plasma output from the damaged mucosa was greater when secretion was stimulated by bethanechol than by histamine. Only minute amounts of glucose crossed the normal mucosa, but large amounts appeared in the gastric contents after damage. Proportionately more sodium than glucose left the damaged mucosa. Vol. output occurred when the mucosa was exposed to acid, but not to neutral soln. Histamine was detected in gastric contents during and following salicylate damage more often than in control experiments. Topical irrigation of the damaged mucosa with histamine caused a small stimulation of acid secretion and a large output of plasma but not of erythrocytes.

- 6154 THE EFFECT OF GASTRIN AND HISTAMINE ON SECRETION OF BILE. (E.) Zaterka, S. (VA Ctr., Los Angeles, Cal.) and M. I. Grossman. Gastroenterology 50(4):500-505, 1966.

Three adult mongrel dogs were subjected to total gastrectomy with esophagojejunostomy, cholecystectomy, and ligation of the minor pancreatic duct. The bile duct was made available for cannulation by insertion of a cannula opposite its papilla. Experiments were started 1 wk. after surgery; dogs were fasted 18 hr. before each experiment which was carried out 2-3 times each wk. Both pure Gastrin II and histamine increased the rate of flow of bile in the unanesthetized dogs. The choleresis caused by gastrin was like that seen with secretin, characterized by an increase in conc. and output of bicarbonate. With stimulation by histamine the bicarbonate conc. of the bile decreased and the chloride conc. increased. Neither gastrin nor histamine produced max. biliary flow rates equal to those attained with secretin.

- 6155 EFFECT OF PARATHYROID HORMONE ON GASTRIC SECRETION AND HUMORAL PARAMETERS. (Sp.) Roseblit, E. (Durand Hosp., Buenos Aires, Argentina), E. Iovine, J. E. Segal, B. Schmukler and A. L. C. Maggi. Prensa Med. Argent. 52(42):2686-2691, 1965.

The effect of parathyroid hormone (200 Units i.v.) on gastric secretion (before and after histamine stimulation) and on blood and/or urine levels of calcium, phosphorus, magnesium, alkaline phosphatase, citric acid, sodium, chlorine, potassium, and mucoprotein was investigated in 12 patients (age 19-79 yr.), of whom 3 were normal, 3 had inactive duodenal ulcer, 3 had active gastroduodenal ulcer, 2 had gastroduodenitis, and 1 was subjected to gastrectomy for duodenal ulcer. No direct effect of parathyroid hormone on gastric secretion was observed; in 1 patient, post-histaminic acid secretion levels were elevated and an increase in calcium levels of blood and gastric juice was observed. Blood and urine studies showed no evidence of hyperparathyroid function in patients with active or inactive gastroduodenal ulcer.

- 6156 SECRETORY ACTIVITY OF THE PANCREAS DURING ATROPHY CAUSED BY PLACING A FISTULA IN THE LARGE DUCT. (Rus.) Toitskaia, V. B. (Pavlov Inst. Physiol., Leningrad, USSR) and E. K. Funtikova. Fiziol. Zhur. SSSR Sechenov. 51(11):1327-1334, 1965.

The study was made on dogs with exposed pancreatic duct and a fistula of the duodenum. In a dog with intact accessory pancreatic duct, following feeding with milk, secretion of pancreatic juice toward the end of 2 mo. was markedly decreased and continued to decrease. At the end of the period of observation (7 mo.) secretion (per 6 hr. period) decreased to 8 ml from an original value of 62 ml. Amyolytic and proteolytic activity of the juice started to decrease after 2 mo. Similar results were found after feeding with meat, although the decline in secretion was more gradual than that after feeding with milk. In another dog with ligated accessory pancreatic duct, feeding with meat resulted in a decrease of total juice from 389-92 ml; enzyme activity was also decreased. Pancreatic juice secretion was decreased by HCl and i.v. secretin.

SECRETION

- 6157 IMMUNOASSAY OF GASTRIC INTRINSIC FACTOR AND THE TITRATION OF ANTIBODY TO INTRINSIC FACTOR. (E.) Irvine, W. J. (Royal Infirm., Edinburgh, Scotland). Clin. Exp. Immunol. 1(1):99-118, 1966.

A simple charcoal method for the qualitative and quantitative immunoassay of intrinsic factor (I) antibody in human serum and the I conc. in gastric juice is described. This technic distinguishes between I and other vitamin B₁₂ (II)-binding substances. False positive results may occur if the serum is withdrawn within 24 hr. after II admin. A good correlation was seen between gastric acid secretion, Co57-II (admin. p.o.) absorption (Schilling test), and the I conc. in gastric juice. As an antigen, I was stable at acid or alkaline pH, but destroyed by heat (56° C for 30 min.). A significant conc. of I antibody in serum was defined as 5 nanogram (mµg) U/ml; II malabsorption (therefore, Addisonian pernicious anemia) was indicated by a secretion of under 100 mµg U/ml of I in the gastric juice during the first 60 min. of histamine stimulation. The serum I antibody titer was over 5 mµg U/ml in 52% of 162 patients with Addisonian pernicious anemia. I antibodies were detected in the sera of 9 of 87 patients with duodenal ulcer, thyroid disease, or pernicious anemia; these patients also showed histamine-fast achlorhydria and II malabsorption, which was corrected by exogenous I. There was a good correlation between the results of immunoassay and bioassay tests of hog I. The dose of hog I required to correct p.o. II absorption (in the Schilling test) in patients with Addisonian pernicious anemia was 300-600 mµg U. It is suggested that hog I preparations should be defined in terms of mµg U of I/mg.

- 6158 EFFECTS OF COLCHICINE ON INTESTINAL MUCOSAL DEHYDROGENASES. I. HISTOCHEMICAL OBSERVATIONS. (E.) Myren, J. (U. Alabama Med. Ctr., Birmingham), G. C. Luketic, R. Ceballos, G. Sachs and B. I. Hirschowitz. Am. J. Dig. Dis. 11(5):394-403, 1966.

After inj. into Swiss mice of a small dose of colchicine (0.24 mg/kg s.c.) there were some minimal histologic changes in the jejunum. After a large dose (1.5 mg/kg s.c.) there were more pronounced histologic changes. The glands showed edema and marked inflammatory reaction 3 hr. after inj. Then followed localized cell necrosis with karyorrhexis or karyolysis. When the mucosa of the jejunum was subjected to a histochemical study of various dehydrogenases (succinic, lactic, glucose-6-phosphate, reduced nicotinamide adenine dinucleotide, and reduced nicotinamide adenine dinucleotide phosphate), some changes in distribution and decreases in staining were noted as early as 10 min. after inj. With the smaller dose of colchicine the most severe changes were found after 24 hr. After 48 hr. there was some regeneration of enzymes. Decreases in the various enzymes were more pronounced after the larger dose.

- 6159 EFFECTS OF COLCHICINE ON INTESTINAL MUCOSAL DEHYDROGENASES. II. BIOCHEMICAL OBSERVATIONS. (E.) Luketic, G. C. (U. Alabama Med. Ctr., Birmingham), G. Sachs, J. Myren, T. Tsuji and B. I. Hirschowitz. Am. J. Dig. Dis. 11(5):404-409, 1966.

Doses of colchicine (0.24 mg/kg) which are smaller than those producing mitotic arrest do decrease the activity of lactic dehydrogenase in mouse intestinal mucosa. Histologically this dose did not produce cell destruction, or inflammatory reaction. The activity of β-glucuronidase, however, was not changed. The anti-mitotic dose of 1.5 mg/kg of colchicine produced a distinct increase in β-glucuronidase activity. Puromycin admin. to mice did not affect the lactic dehydrogenase activity in the intestinal mucosa over a period of 60 hr. after admin. Thus, it appears that the effect of colchicine on lactic dehydrogenase activity is not secondary to inhibition of protein synthesis. The action of colchicine on various enzymes may be independent of its action on the mitotic apparatus, and certainly precedes it.

- 6160 THE DISTRIBUTION AND FUNCTIONAL CHANGES OF GASTRIC UREASE ACTIVITY. (E.) Maramaa, S. (Tartu State U., Estonia, USSR). Gastroenterology 50(5): 657-664, 1966.

SECRETION

Frozen dog and cat gastric mucosa was cut in 30 micron-thick sections parallel to the surface of the mucosa. Urease was determined by the histochemical method of Holter and Linderström-Lang. Urease activity was present in both the parietal and mucoid cells of the gastric mucosa. In the parietal cells urease was present in all of the animals investigated. Activity was higher in the lesser curvature than the greater curvature. Stimulation of secretion by feeding and histamine inj. increased urease activity in the parietal cell zone. Urease activity in the fundic surface epithelium was low in the resting state, but increased markedly during stimulation of secretion. About two-thirds of the animals exhibited urease activity in the pyloric mucosa. The present data support the view that urease is of cellular origin and that bacterial sources cannot account for its occurrence at subepithelial levels.

- 6184 EVALUATION OF THE PROTEOLYTIC ACTIVITY OF PEPSIN BY COLORIMETRIC MICRO-DETERMINATION. (Fr.) Beck, J. (Biol. Franc. Indust., S. A., Gen-nevilliers, Seine, France). Ann. Pharm. Franc. 24(2):109-116, 1966.
After reviewing the various methods for the evaluation of the proteolytic activity of pepsin, the author discusses some of the advantages of the Nelson colorimetric micromethod. These include the use of indigo carmine fibrin (whose pigment is found in the free state and does not combine with the products of enzymatic digestion or degradation), simplified technic, rapid obtaining of results, and use of normal laboratory equipment. The author presents various modifications of the procedure pertaining to the volume of the reacting medium, the duration of the enzymatic reaction, the ratio of enzyme to substrate, and the dispersion of the substrate. Results are reported for 20 trials with crystallized pepsin. Data is presented confirming the parallel liberation of nitrogen and the stain in the hydrolyzing liquid. Comparison with the Codex 1949 (France) method for the determination of the proteolytic activity of pepsin is made. Results are reported from previous experiments in which the method was applied to the determination of pepsin in the gastric juice of rats. The new method permits evaluation of quantities as small as 1-3 μ g of crystallized pepsin.
- 6185 PROTEOLYTIC ACTIVITY IN THE HUMAN STOMACH DURING DIGESTION AND ITS CORRELATION WITH THE AUGMENTED HISTAMINE TEST. (E.) Rune, S. J. (Bispebjerg Hosp., Copenhagen, Denmark). Gut 7(1):69-72, 1966.
Eighty subjects were admin. via an intragastric catheter a standard liquid meal which contained 10% protein and a tracer amount of ^{131} I-albumin. Small samples of gastric contents were aspirated at 10, 30, 50, 70, and 90 min. after ingestion of the meal. The percentage of ^{131} I-albumin digested at 50 min. was employed as an index of proteolytic activity in the stomach. A highly significant correlation was found between proteolytic activity during food digestion and the gastric secretion of acid during the augmented histamine test. A low but significant correlation was found between proteolytic activity and the basal secretion of acid. The av. proteolytic activity in 18 patients with duodenal ulcer was 42% (S.D. = 13%) compared with 26% (S.D. = 12%) in 20 normal individuals. This difference is highly significant.
- 6186 DIGESTION AND ABSORPTION IN TOTALLY DEPANCREATIZED DOG, WITH SPECIAL REFERENCE TO THE INFLUENCE OF ESTROGEN ON DIGESTION AND ABSORPTION OF FAT. (E.) Fukaya, K. (Kanazawa U. Sch. Med., Japan). Nippon Geka Hoka (Arch. Jap. Chir.) 35(2):253-267, 1966.
Adult mongrel dogs of both sexes weighing approx. 10 kg were subjected to total pancreatectomy. Groups of dogs were given 1-2 U of insulin (Isuzilin), 1,000 U of estradiol benzoate, or both drugs each day. Metabolic studies were performed after the dogs were given a standard meal consisting of a special bread, milk and water. The food incorporated some chromium oxide. Compared to intact animals, the mean crude absorption rate of fat, protein and carbohydrate after insulin only was resp., 29.1%, 24.9%, and 67.3%, resp.; after estrogen only 33.7%, 21.9% and 71.4%; and after combined insulin and estrogen 82.1%, 34.0%, and 83.5%. Oleic acid labeled with ^{131} I was admin. to some dogs after admin. of Lugol's soln. on the previous day. In dogs given both insulin and estrogen, the max. rate of absorption of the oleic acid into the blood was 5.25% at hr. 4 of the test and absorption rate in feces was 10.8%. In dogs given only insulin max. absorption was 0.41% after hr. 6 and absorption rate in feces was 26.5%. While total bile and total cholesterol was not markedly different in the depancreatized compared to intact dogs, there was decreased hepatic bile and phospholipids. Simultaneous insulin and estrogen tended to restore these values towards the normal. The lowest wt. loss was seen in the dogs that received both insulin and estrogen.

DIGESTION

- 6187 THE EFFECT OF SMOKING ON THE ASSIMILATION OF FOODSTUFFS IN EXPERIMENTAL ANIMALS. (Rus.) Gogol, A. T. (Cent. Inst. Postgrad. Med. Train., Moscow). Vop. Pitan. 24(6):23-26, 1965.
In adult, male rats fed for 7 days with either smoked sausage or sausage treated with a liquid compound which simulated the smoking procedure, there was an increase in the assimilation of proteins, fats, and carbohydrates of the diet compared to controls fed only boiled sausage.
- 6188 ACTIVATION OF TRYPSINOGEN AND PLASMINOGEN BY THROMBIN PREPARATIONS. (E.) Engel, A. (Harvard Med. Sch., Boston, Mass.), B. Alexander and L. Pechet. Biochemistry (Wash.) 5(5):1543-1551, 1966.
When purified thrombin was added to trypsinogen or plasminogen and the mixtures were assayed for esterolytic and caseinolytic activities, both zymogens were rapidly and progressively activated in accordance with enzyme kinetics. That this was due to thrombin rather than to possible contaminants in the thrombin preparations was demonstrated by means of appropriate inhibitors, by procedures known to terminate thrombin action, and by separation of certain known contaminants. Thus when the preparation was subjected to starch gel electrophoresis, no thrombin was lost. However, expressates from starch that were devoid of thrombin but rich in Factors VII and X were inert on both trypsinogen and p-toluenesulfonyl-L-arginine methyl ester. During trypsinogen activation trichloroacetic acid soluble ninhydrin-staining material was released in parallel with the appearance of esterolytic activity. Thrombin activation of trypsinogen was about two-thirds that by trypsin, but plasminogen activation by thrombin was much higher.
- 6189 DIGESTION AND ABSORPTION OF MALTOSE IN RATS INFECTED BY THE NEMATODE Nippostrongylus brasiliensis. (E.) Symons, L. E. A. (C.S.I.R.O., McMaster Lab., Glebe, New South Wales, Australia). Exp. Parasit. 18(1): 12-24, 1966.
Male albino rats (100-200 g) were subjected to maltose test meals (800 or 1,200 mg) 10 days after s.c. inj. of 4,000 infective larvae of N. brasiliensis; this is the time of greatest effect of the parasite. There was little loss of efficiency when digestion and absorption of maltose were measured in the intact rat, except in severely affected animals in which the rate of digestion was reduced and the luminal retention of glucose increased in the earlier stage of absorption of the test meal. In these animals failure of function was more apparent in the distal two-thirds of the small intestine than in the proximal one-third. It was only in severely affected rats that appreciable amounts of maltose and glucose passed into the large bowel.
- 6190 SEARCH FOR A NATURALLY OCCURRING AMYLASE INHIBITOR IN HUMAN SERUM. (E.) Hayashi, S. (Los Angeles Co. Gen. Hosp., Cal.), R. L. Searcy, J. E. Berk and E. M. Hardy. Nature (London) 210(5031):92-94, 1966.
When the dinitrosalicylic acid method was used to investigate the distribution of amylase activity in normal and abnormal sera before and after paper electrophoresis, in no instance did subjection to electrophoresis greatly increase amylase activity. In an attempt to demonstrate an amylase inhibitor, aliquots of pooled normal human serum were subjected to electrophoresis in duplicate. The segments from one strip were eluted with saline, whereas those of the other strip were treated with a mixture of saline and serum. After correction for the amylase activity of the serum in the saline-serum mixture, the electrophoretic distributions of saccharogenic activity were similar in both types of eluates; recovery of serum amylase in both cases was about 80%. When serum pooled from normal subjects was tested for amylase activity (using the saccharogenic technic), there was little loss in activity after incubation at 45°C for 16 hr. When pooled serum from patients with acute pancreatitis was tested in the same manner, after 16 hr. incubation at 45°C, more than half of the amylase activity was lost.

DIGESTION

- 6191 ADAPTATION OF THE RATE OF PANCREATIC AMYLASE AND CHYMOTRYPSINOGEN BIOSYNTHESIS TO STARCH- OR PROTEIN-RICH DIETS. (Fr.) Reboud, J. P. (U. Marseille Fac. Sci., France), G. Marchis-Mouren, L. Paséro, A. Cozzone and P. Desnuelle. Biochim. Biophys. Acta 117(2):351-367, 1966.
The rate of biosynthesis of pancreatic amylase and chymotrypsinogen was determined in Wistar rats fed a starch-rich (diet G; 75% starch or glucose and 15% casein) or protein-rich diet (diet P; 70% casein or amino acids and 20% starch) following i.v. inj. of precursor (labelled valine) and in slices of pancreas from diet G- or diet P-fed rats incubated in the presence of precursor. Radioactivity measurements on pancreatic juice samples collected from injured animals, and chase experiments with pancreas slices, have shown that no loss of labelled enzymes by secretion and degradation is likely to occur during the assay. As compared to diet P, results indicate that the ingestion of diet G induces an 8-fold increase in the rate of biosynthesis of amylase and a 2-fold decrease in that of chymotrypsinogen. Since results with incubated pancreas slices were similar to those obtained in vivo, it is suggested that the diet determines a specific modification in the biosynthesis mechanism of the acinar cells of the pancreas.
- 6192 PROTEOLYSIS IN BLOOD SERUM AND POLAROGRAPHIC MEASUREMENT OF TRYPSIN AND ITS INHIBITOR. (Cz.) Homolka, J. (Charles U., Prague, Czech.). Cas. Lek. Cesk. 105(10):268-269, 1966.
- 6193 α_2 -ANTI-TRYPSIN ACTIVITY AND DIFFERENT TRYPSIN SUBSTRATES. (E.) Ganrot, P. O. (U. Lund, Sweden). Clin. Chim. Acta 13(4):518-521, 1966.
- 6194 DIGESTIVE JUICES AND FOOD INTOLERANCE IN NEWBORN AND NURSING INFANTS. (It.) (Rev.) Ferlazzo, A. (U. Messina, Italy) and P. Minicuci. Rass. Clin. Ter. 65(1):22-68, 1966.
- 6195 STRUCTURE AND ACTIVITY OF PANCREATIC RIBONUCLEASE OF THE RAT. (Fr.) Beintema, J. J. (Royal U., Groningen, The Netherlands) and M. Gruber. Bull. Soc. Chim. Biol. (Paris) 47(12):2307-2310, 1965.

MOTILITY

- 6196 MOTOR RESPONSE OF THE CANINE STOMACH TO INSULIN AND FEEDING. (E.) Nelsen, T. S. (300 Pasteur Dr., Palo Alto, Cal.), E. H. Eigenbrodt and L. A. Keoshian. Arch. Surg. (Chicago) 92(3):379-385, 1966.
Gastric motility was studied in 12 unanesthetized dogs by means of extraluminal transducers surgically implanted on the serosal surface of the stomach parallel to the circular muscle. In the fasting state the rate of contractions ranged from 4-5.5/min. and the contractions were usually propagated from the body of the stomach to the pylorus. Insulin (12-15 U i.v.) abolished gastric contractions for 15-20 min., then produced regular strong contractions with a significant increase in rate (av. 6.3/min.). Feeding a 250-g meal produced a significant decrease in the amplitude and rate of contractions (av. 4.4/min.).
- 6197 MECHANISM UNDERLYING THE AUGMENTATION OF INTESTINAL MOTILITY PRODUCED BY STIMULATION OF THE SPLANCHNIC NERVE. (Jap.) Fukuda, H. (Okayama U. Sch. Med., Japan). Nippon Seirigaku Zasshi (J. Physiol. Soc. Jap.) 28(2):45-52, 1966.
Intestinal (jejunum) motility was studied in dogs after pretreatment with reserpine (1 mg/kg/day s.c.) for 2 successive days. Stimulation of the major splanchnic nerve produced a marked increase in motility; this effect did not appear 25 min. after i.v. admin. of 0.1 mg/kg of atropine. Similar increase in motility appeared after stimulation of ventral roots of thoracic nerves VII-X, but no effect was seen after stimulation of the dorsal roots of thoracic nerves VI-X. When nicotine was applied to the celiac and superior mesenteric ganglia, splanchnic nerve stimulation no longer increased intestinal motility. Stimulation of the mesenteric nerve increased intestinal motility; vagus or sympathetic nerve resection had no effect on this response, but hexamethonium (5 mg/kg i.v.) practically abolished response to mesenteric nerve stimulation after 7 min., with the effect reappearing after 18 min. Results indicate that the fibers which produce the stimulatory effect described above on intestinal motility are connected with cholinergic intrinsic neurons. In dogs not previously treated with reserpine but subjected to vagus resection, mesenteric nerve stimulation generally produced an inhibitory effect on intestinal motility; this response was unchanged following inj. of hexamethonium. This indicates that a cholinergic intrinsic neuron is not involved.
- 6198 EFFECT OF VARIOUS NARCOTIC ANALGESICS ON THE PYLORIC SPHINCTER IN RATS. INTERPRETATIVE TRIALS. (Fr.) Harichaux, P. (U. Tours Sch. Med. Pharm., France) and J. Moline. C. R. Soc. Biol. (Paris) 159(10):2024-2026, 1965.
The effect of i.v. inj. of various narcotic analgesics on the pyloric sphincter was studied in male rats. Morphine hydrochloride (0.5-1 mg/kg) caused an increase in flow through the pylorus (40-100%) lasting 5-15 min. in 19 of 22 rats; a decrease in frequency of contractions (3 per min.) was also observed. Dextromoramide caused spasm of the pylorus and reduction of flow (4 of 6 animals), but was very toxic even at doses as low as 75-400 µg/kg. Diphenoxylate (0.8-5 mg/kg) decreased flow through the pylorus by 50% for 6-30 min. in 11 of 14 animals; this effect was inhibited by papaverine. Meperidine hydrochloride (0.8-2.5 mg/kg) slightly increased pyloric flow for 3-10 min. in 14 of 18 animals without affecting the frequency. Papaverine hydrochloride (0.8-2.5 mg) increased pyloric flow 30-50% in 7 of 9 animals; in 8 animals the effect of papaverine was inhibited by barium chloride and acetylcholine. It is concluded that the narcotic analgesics have the same central action, but their peripheral effects are different.
- 6199 QUANTITATIVE ANALYSIS OF HUMAN BILIARY EVACUATION WITH A RADIOISOTOPIC TECHNIQUE. (E.) Englert, E., Jr. (U. Utah Coll. Med., Salt Lake City) and V. S. W. Chiu. Gastroenterology 50(4):506-518, 1966.
A method for the study of biliary motility in resting man was described. It

MOTILITY

employed a cholecystographic agent (iopanoic acid) labeled with 5-20 μ c of γ -emitting ^{131} and appropriate apparatus for measurement of radioactivity in the gall-bladder region. With physiologic stimulation, radioactivity diminished irregularly for a variable time and became steady. The period of decrement was not exponential, but an exponential function could be fitted to it approx. to derive a measurement of overall emptying rate at the half-time of emptying. The amounts of radioactivity before and after emptying provided a measure of overall emptying efficiency as the per cent of emptying. Analysis of the period of radioactive decrement uncovered numerous changes in its rate. Generally these components of biliary evacuation began inefficiently and became effective after an av. interval of 21 min., often with a single productive phase. Physiologic stimulation with fatty meals and continuous i.v. cholecystokinin gave somewhat similar results. Rapid i.v. cholecystokinin induced brief and incomplete biliary evacuation.

- 6200 METHOD OF ELECTRO- AND MECHANOGRAPHIC STUDIES OF THE STOMACH AND DUODENUM, WITH X-RAY CONTROL FOR CORRECT PLACING OF THE DIFFERENT ELECTRODE OF APPARATUS EGS-3. (Rus.) Grigoriev, V. G. and S. I. Kruk. Ter. Arkh. 38(1):112-117, 1966.

In studies on 25 patients, a comparison was made of recordings of the activity of different portions of the stomach and duodenum made by two different technics: mechanograms which utilized the balloon-kymograph technic, and electrographs which record the electric potential from the surface of the abdomen (using apparatus EGS-3). Results show that the electropotential of the stomach is closely related to its motor function. During hunger contractions of the duodenum, the electric potential of the stomach is the one recorded because it has the higher potential of the two organs. In studies performed after eating, during peristalsis, the electrograph records the contractions of both the duodenum and stomach. Electrogastrographic study of the motor function of the stomach is best made in subjects in the "satiated" condition. In studies of the motor function of the antrum (and sometimes of the body), the electrogastrographs show no interference from aperiodic high-amplitude electric potentials coming from the bowel. As the projection areas of the gastrointestinal segments of the anterior abdominal wall are variable, their study requires preliminary X-ray control for correct fixation of the intra-abdominal electrode.

- 6201 OCCLUSION OF THE JEJUNUM FOR INTESTINAL PERFUSION IN MAN. (E.) Phillips, S. F. (U. Minnesota, Rochester) and W. H. J. Summerskill. Mayo Clin. Proc. 41(4):224-231, 1966.

A 4-lumen tube with a balloon was passed by 28 healthy volunteers (19 male, 9 female). The balloon was positioned at the duodenojejunal junction. Suction could be applied proximal and distal to the balloon. When sulfobromophthalein was inj. i.v., more than 99.9% was recovered above the balloon, indicating very little leakage past the balloon when adequately inflated. When phenol red was instilled below the balloon, continuous suction proximally led to the recovery of only 0.4% of the dye; when infused above the balloon, 6.0% was recovered below the balloon. Motor activity distal to the balloon was reduced during inflation when compared with findings before or afterward. Motor activity was always less in the second of 2 control periods. The vol. of mixed secretions recovered from above the balloon ranged from 1-160 ml/30 min. (mean 48 ml); simultaneous aspiration beyond the balloon yielded 0-5 ml (mean 2 ml).

- 6202 EVIDENCE FOR AN INTESTINAL INHIBITOR OF VILLOUS MOTILITY. (E.) Kokas, E. (U. North Carolina Sch. Med., Chapel Hill) and C. L. Johnston, Jr. Arch. Int. Pharmacodyn. 160(1):211-222, 1966.

Crude mucosal extracts made from the entire small intestine of fasted dogs were treated with charcoal and then fractionated by continuous flow electrophoresis. The 6 ninhydrin positive fractions were tested by i.v. inj. into fasted,

MOTILITY

anesthetized dogs. Villous motility was evaluated by direct observation of villi in a jejunal loop. These fractions were identified by number, in ascending order, according to speed of migration. Fraction IV contained villikinin. Of the remaining fractions, only Fraction III influenced villous motility. Initially villi were slowed below the basal rate. When increasing doses of the crude extract were given, first there was increased villous motility while with larger doses eventually there was decreased activity. When the crude extract was dialyzed, only the dialyzed extract showed inhibition of villous motility. For convenience the inhibitory material has been called antivillikinin. Antivillikinin was shown to be different from other inhibitors of gastrointestinal hormones.

6203 ROLE OF THE B-COMPLEX VITAMINS ON INTESTINAL ACTIVITY IN DOGS. (E.)

Kopidakis, M. (New Jersey Coll. Med. Dent., Jersey City) and E. J.

Lazaro. Canad. J. Surg. 9(2):184-192, 1966.

Motility studies were conducted in young or old dogs (2 or 8 yr.) with Thiry-Vella isolated-loop fistulas of the jejunum or sigmoid colon. Vitamin B complex caused a slight increase in colon motility (measured in the isolated loop), which was propulsive in the young animals but not in the old dogs. Thiamine caused a moderate, non-propulsive increase in jejunal activity and a marked, propulsive increase in colon motility in young animals; its effect in old animals was not studied. Pyridoxine caused a moderate increase in activity at both sites in young dogs, with a slight retropropulsive activity in the jejunum and a marked propulsive action in the colon; it had no effect on colon motility in the old dogs. Pantothenic acid caused a moderate increase in motility at both sites in young dogs and a slight increase in colon activity in old dogs; this activity was propulsive only in the colon of young dogs. Nicotinamide had no significant effect on intestinal motility. It is concluded that older patients need larger doses of the B vitamins than younger patients, to promote intestinal activity after abdominal or other surgery. Nicotinamide may prolong hypoperistalsis under some conditions. Pantothenic acid, thiamine, and pyridoxine seem to be of value in preventing paralytic ileus.

6204 INHIBITION OF GASTRIC SECRETION AND MOTILITY BY FAT IN THE INTESTINE.

(E.) Swan, K. G. (VA Ctr., Los Angeles, Cal.), S. J. Konturek, E. D.

Jacobson and M. I. Grossman. Proc. Soc. Exp. Biol. Med. 121(3):840-844, 1966.

The effect of an emulsified fat (Lipomul, 67% fat) or a micellar fat (2.5% fat with canine bile) was studied on gastric motility and gastrin-stimulated (10 g/hr. i.v.) gastric secretion in 4 groups of Heidenhain pouch dogs: pouch only (3 dogs); pouch with gastric fistula (2 dogs); pouch with Thiry loops of duodenum and jejunum (4 dogs); and pouch with removal of the duodenum and drainage of bile and pancreatic juice into the jejunum (4 dogs). A dose of 30 g of emulsified fat or 3 g of micellar fat placed into the stomach (duodenum intact) produced a significant inhibition of gastric secretion (54% and 35%, resp.) while 3 g of emulsified fat did not inhibit secretion. Gastric motility was depressed in 100% of the experiments by the high dose of emulsified fat and 83% by the micellar fat, but only 20% by the low dose of emulsified fat. In the duodenectomized dogs, 30 g of emulsified fat or 3 g of micellar fat placed in the stomach still significantly inhibited gastric secretion (25% and 37%, resp.), but motility was inhibited in only half the number of experiments as in the intact dogs. The micellar fat preparation placed directly into the Thiry loops of the duodenum or jejunum did not produce a significant change in secretion or motility.

6205 ELECTRICAL RESPONSES OF SMOOTH MUSCLE TO EXTERNAL STIMULATION IN HYPERTONIC SOLUTION. (E.) Tomita, T. (U. Oxford, England). J. Physiol.

(London) 183(2):450-468, 1966.

Exposure of guinea pig taenia coli to Krebs solution, made twice hypertonic by addition of sucrose, abolished mechanical movement and stopped spontaneous electrical

MOTILITY

activity, but the electrical response to intracellular stimulation was similar to that seen in physiologic soln. Cathodal stimulation depolarized the cells and produced spike potentials while anodal stimulation hyperpolarized the cells and only produced spikes with weak stimuli. When both stimulating electrodes were placed close together at one end of the tissue, the extrapolar polarization (recorded intracellularly) changed polarity at 1-2 mm from the stimulating electrode. This reversed polarity was no longer observed when an insulating partition was placed between the stimulating and recording site. The relationship between extracellularly applied current and intracellularly recorded potential showed that membrane resistance decreased with depolarization and slightly increased with hyperpolarization. Long anodal current often produced electrical activity of low amplitude. Cessation of a strong and long anodal current was followed by slow depolarization which sometimes triggered a spike potential.

- 6206 ON THE MECHANISM OF ACTION OF MAGNESIUM SULPHATE UPON THE GALLBLADDER. (E.) Crema, A. (U. Pavia, Italy), G. Benzi, G. M. Frigo and F. Berté. *Gastroenterologia (Basel)* 105(2):109-114, 1966.

The urine of 15 fasting volunteers was collected 3 hr. before and 2 hr. after admin. by mouth of 40 ml of a 33% soln. of $MgSO_4$. Extracts of the urine were made by the method of Svatos which utilizes benzoic acid. The cholecystokinetic effect was determined *in situ* in monkeys and guinea pigs; isolated guinea pig gallbladders were also tested in an organ bath perfused with the blood of donor animal (monkey or guinea pig). The extract from $MgSO_4$ -treated volunteers caused a significant increase in cholecystokinetic activity when related to that of a standard preparation. Both in the guinea pig and monkey, perfusion of $MgSO_4$ through the duodenum caused the gallbladder to contract. The extracts had no effect on jejunum or on blood pressure.

- 6207 EFFECT OF SECRETIN AND CHOLECYSTOKININ-PANCREOZYMIN EXTRACTS ON GASTRIC MOTILITY IN MAN. (E.) Johnson, L. P. (U. Washington Sch. Med., Seattle), J. C. Brown and D. F. Magee. *Gut* 7(1):52-57, 1966.

Gastric motility (utilizing a balloon) was studied in 8 normal adults after the admin. over a 10-min. period of 0.5 U/kg of 2 duodenal extracts. Secretin extracts (all from the same batch) produced variable results with an initial increase in intragastric pressure and motor activity, followed by subsequent clear inhibition in 4 subjects. Secretin led to some inhibition of motor activity in 7 of the 8 subjects; the reduction in mean frequency of amplitude was not significant, and the reduction in mean amplitude index (the summation of amplitude of all waves) was of questionable significance. Cholecystokinin-pancreozymin extracts induced prompt, complete and more prolonged gastric motor inhibition in each of the subjects. In every category of measurement used, these reductions in gastric activity were statistically significant. The recently reported cholecystokinin-pancreozymin inhibition of gastric acid secretion, coupled with its inhibition of motility, makes it apparent that this material is capable of reproducing the physiological activity of fat in the duodenum. It is speculated that this material may contain or even be enterogastrone.

- 6208 THE ELECTRICALLY STIMULATED ILEUM OF THE GUINEA-PIG FOR MEASURING ACETYLCHOLINE ANTAGONISM AT DIFFERENT SITES. (E.) Leach, G. D. H. (Bradford Inst. Techn., England). *J. Pharm. Pharmacol.* 18(5):265-270, 1966.

Adult guinea pigs (300-500 g) were sacrificed and 3-5 cm of ileum removed from the small intestine 20 cm proximal to the ileocecal junction. Longitudinal muscle movements were isometrically recorded on smoked paper using a photoelectric method after transmural stimulation of the preparation with platinum electrodes. The antagonistic effect of hexamethonium and atropine on longitudinal muscle response and the emptying reaction (coordinated movement of circular and longitudinal muscles) was

MOTILITY

determined. The emptying reaction was inhibited by hexamethonium in conc. of 1.5-6.0 $\mu\text{g/ml}$, while conc. as high as 8-10 $\mu\text{g/ml}$ failed to depress the longitudinal response more than 50% of its original height. On the contrary, atropine in conc. of 0.001-0.02 $\mu\text{g/ml}$ reduced the longitudinal response without affecting the emptying reaction. Results indicate that the preparation discriminates satisfactorily between drugs which antagonize acetylcholine at its nicotinic and muscarinic site.

- 6209 SOME OBSERVATIONS ON THE RESPONSE OF NORMAL HUMAN SIGMOID COLON TO DRUGS IN VITRO. (E.) Wright, P. G. (Makerere U. Coll., Kampala, Uganda) and J. J. Shepherd. Gut 7(1):41-51, 1966.

Normal human sigmoid colon was obtained from 76 preparations of colon from 14 male African patients. Strips of longitudinal and circular muscle were allowed to come to equilibrium in an organ bath for about 40 min. before drugs were added. Low conc. (less than 10^{-5}) and short contact time (up to 1 min.) with nicotine or dimethylphenylpiperazinium invariably caused inhibition. Concentrations of 10^{-5} and longer contact times produced immediate inhibition succeeded later by contraction. With higher conc. contraction more rapidly succeeded inhibition. Still higher conc. caused inhibition succeeded immediately by contraction which was then shortly followed by inhibition. Depending on conditions, these observations suggest that the 2 drugs can produce both inhibitory and contractile responses in both circular and longitudinal colonic muscle. A conc. of nicotine which alone produces a biphasic response will produce only inhibition in the presence of hyoscine. Neostigmine annulled inhibition and made contraction greater. Subsequent relaxation is hastened by neostigmine. Neither pronethalol nor bretylium (in the conc. used) had much effect on the response to acetylcholine. Neither neostigmine or hyoscine (in the conc. used) affected the response to epinephrine. Longitudinal muscle is contracted by 5-hydroxytryptamine but circular muscle is usually inhibited.

- 6210 MEMBRANE POTENTIAL AND ION CONTENT IN THE SMOOTH MUSCLE OF THE GUINEA-PIG'S TAENIA COLI AT DIFFERENT EXTERNAL POTASSIUM CONCENTRATIONS. (E.) Casteels, R. (U. Oxford, England) and H. Kuriyama. J. Physiol. (London) 184(1):120-130, 1966.

Electrophysiologic studies are presented of the guinea pig's taenia coli smooth muscle. Isotonic soln. in which the sum of NaCl + KCl was constant did not produce swelling of the smooth muscle, even at high $[\text{K}]_o$, and did not change the intracellular chloride conc. Addition of an equivalent amount (118 mM) of NaCl or KCl to Krebs soln. produced the same loss of water. Solutions in which the product $[\text{K}][\text{Cl}]$ was kept constant decreased the internal chloride conc. so that the chloride equilibrium potential became temporarily positive and returned only after 2 hr. to a negative value. From these results and the finding that even in normal Krebs soln. E_{Cl} was about 35 millivolts more positive than the membrane potential, it is concluded that the chloride ions are not passively distributed. The potassium equilibrium potential is the main factor in the generation of the membrane potential. The large discrepancy between the two can be explained by the non-passive chloride distribution and by the sodium permeability of the membrane. The maintenance of the normal cell vol. in soln. with constant sum of NaCl + KCl is explained by the constant intracellular chloride conc.

- 6211 THE ACTION OF OUABAIN ON THE SMOOTH MUSCLE CELLS OF THE GUINEA-PIG'S TAENIA COLI. (E.) Casteels, R. (U. Oxford, England). J. Physiol. (London) 184(1):131-142, 1966.

The action of 10^{-6} g/ml of ouabain on the smooth muscle of the guinea pig's taenia coli was studied utilizing extracellular recording (sucrose-gap method) and intracellular recording. This ouabain conc. produced a depolarization of the membrane, accompanied by an initial increase of the spike frequency and later a depolarization block. Removal of the ouabain produced a sudden and pronounced hyperpolarization leading to a block of spike discharge. Reduction of the external sodium conc.

MOTILITY

or an increase of the external calcium conc. or exposure to 10^{-7} g/ml epinephrine repolarized the cell membrane in the presence of ouabain. Ouabain decreased the tension development of the taenia coli. Ouabain decreased the intracellular potassium and chloride and increased the intracellular sodium conc. However, the corresponding changes of the equilibrium potentials were not sufficient to explain the changes of the membrane potential. A possible explanation for the action of ouabain is presented suggesting that the drug may decrease the calcium binding properties of the cell membrane.

- 6212 **INTESTINAL PROPULSION IN RESTRAINED AND UNRESTRAINED RATS.** (E.)
Brown, M. S. (U. Pennsylvania Sch. Med., Philadelphia) and W. G. Groves.
Proc. Soc. Exp. Biol. Med. 121(4):989-992, 1966.
Male Wistar rats, after being allowed only water for 24 hr., were given by gavage a test meal which consisted of a suspension of charcoal powder in 0.5% tragacanth. Immediately after the test meal each experimental rat was restrained by taping together the forelimbs and the hindlimbs and taping the tail to the body. Each was then wrapped in a piece of galvanized steel window screen molded to the contour of the animal's body. After sacrifice between 5 and 45 min., the velocity of the meal in unrestrained rats was related inversely to the time after dosing, and declined exponentially with increasing distance from the pylorus. With every advance of 11% of the intestinal length, the velocity was halved. When the rats were restrained, these relationships generally persisted despite a reduction in the overall velocity with which the meal traversed the intestine. Dichloroisoproterenol partially reversed the decrease in velocity in the restrained animals.
- 6213 **CLINICAL SIGNIFICANCE OF MOTOR DISTURBANCES OF THE ENTEROCOLONIC SEGMENT.** (E.) Schuster, M. M. (Johns Hopkins U. Sch. Med., Baltimore, Md.). Am. J. Dig. Dis. 11(4):320-335, 1966.

HEPATIC METABOLISM

- 6218 DENSITY GRADIENT CENTRIFUGATION OF LIVER MITOCHONDRIA FROM NORMAL AND THYROTOXIC RATS. (E.) Greif, R. L. (Cornell U. Med. Coll., New York, N. Y.), J. A. Alfano and E. Eich. Endocrinology 78(4):733-736, 1966.
Rats employed were adult male albinos (Charles River). Mitochondria isolated from livers of euthyroid rats are distributed in a single band on centrifugation through a linear density gradient of 37-52% sucrose. Mitochondria swollen by preincubation at 37°C or isolated from livers of severely thyrotoxic rats are distributed either in 2 bands or in a single band of increased sucrose density. The results suggest that mitochondria isolated from the same sample of rat liver differ in their responses to conditions producing swelling.
- 6219 OBSERVATIONS ON THE NATURE OF THE HEAT-RESISTANT THYROXINE DEIODINATING SYSTEM OF RAT LIVER. (E.) Galton, V. A. (Dartmouth Med. Sch., Hanover, N. H.) and S. H. Ingbar. Endocrinology 78(4):855-859, 1966.
Rat liver slices incubated for 15 min. in Krebs-Ringer phosphate buffer before incubation in the buffer plus glucose showed a loss of heat-resistant deiodinating activity. This loss of activity in slices appeared to be due to the loss of diffusible components during preparation, since slices placed immediately after slicing into the incubation medium demonstrated the heat-resistant deiodinating activity. Heat-resistant activity was restored to leached or dialyzed slices when they were resuspended for incubation with thyroxine either in buffer plus glucose previously exposed to unleached slices or in buffer plus glucose containing the dialyzable factors from unleached slices. In unboiled systems, deiodinating activity was reduced by leaching or dialysis. Deiodinating activity was also observed in the leaching medium, but not in the dialysate, incubated without slices. It was concluded that rat liver contains at least 2 mechanisms for the deiodination of thyroxine. One is heat resistant and is probably not physiological. The other is destroyed by heat and thus may represent enzymic deiodination.
- 6220 HYPERTROPHY OF THE AGRANULAR ENDOPLASMIC RETICULUM IN HAMSTER LIVER INDUCED BY PHENOBARBITAL. (WITH A REVIEW ON THE FUNCTIONS OF THIS ORGANELLE IN LIVER.) (E.) Jones, A. L. (Harvard Med. Sch., Boston, Mass.) and D. W. Fawcett. J. Histochem. Cytochem. 14(3):215-232, 1966.
Golden hamsters of both sexes received subanesthetic doses of phenobarbital (300-320 mg/kg total divided over a period of 3-4 days, i.p.). Animals were fasted for 24 hr. after the last inj. and before being killed. Electron examination of the liver of treated animals showed a very marked hypertrophy of the agranular reticulum and a depletion of particulate glycogen. The increase in smooth endoplasmic reticulum cannot be explained by loss of ribosomes from the granular reticulum and is regarded as an absolute gain of new membrane. Numerous examples of continuity between granular and agranular reticulum were noted, and it is suggested that protein synthesis associated with the granular reticulum contributes to the formation of the new smooth-surfaced membranes. A review of literature indicates that the agranular reticulum plays an important role in hydroxylation and elimination of lipid-soluble drugs, and in cholesterol and steroid hormone metabolism.
- 6221 METABOLISM OF DRUGS AND CARCINOGENS BY HUMAN LIVER ENZYMES. (E.) Kuntzman, R. (Wellcome Res. Lab., Tuckahoe, N. Y.), L. C. Mark, L. Brand, M. Jacobson, W. Levin and A. H. Conney. J. Pharmacol. Exp. Ther. 152(1):151-156, 1966.
Human liver contains enzyme systems which catalyze the ring hydroxylation of 3,4-benzpyrene, the side chain oxidation of pentobarbital, and O-dealkylation of acetophenetidin and the N-dealkylation of 3-methyl-4-monomethylaminoazobenzene.

HEPATIC METABOLISM

In studies on liver homogenates, 3,4-benzpyrene hydroxylation by both human or rat liver was proportional to the amount of tissue in the range from 0.5-10 mg of liver (wet wt.). The male rat contains more of the hydroxylase activity than human liver. The microsomal fraction contained most of the hydroxylase activity in human and rat liver and both required reduced triphosphopyridine nucleotide for activity. Human liver metabolized pentobarbital to a lesser extent than liver from the male rat. With use of C^{14} -labeled drug, upon chromatography, a small radioactive peak was seen near the origin in rat liver which was not seen in human liver. The major radioactive peaks were similar in human and rat liver. No sex difference in the metabolism of acetophenetidin was seen in the rat liver. 3-Methyl-4-monomethyl-aminoazobenzene was metabolized by human liver at a slower rate than by male rat liver.

- 6222 RIBONUCLEASE ACTIVITY IN HEPATIC NUCLEI DURING DEVELOPMENT. (E.) Bresnick, E. (Baylor U. Coll. Med., Houston, Tex.), J. Sage and K. Lanclos. Biochim. Biophys. Acta 114(3):631-633, 1966.

Nuclear ribonuclease was studied in the liver of the fetuses and rats of different stages of development. The specific activity was more pronounced in the newborn rat (5-10 days) and in the fetus (day 18-19) and rapidly diminished until the weanling stage, when the specific activity was 170% of the adult value. A similar pattern was seen for hepatic nuclear DNA. The behavior of the nuclear ribonucleases in the livers at various stages of development were identical when examined in regard to pH optimum, heat stability, Arrhenius plots, and inhibition by polyvinyl sulfate. It is not known whether the increased activity in the young rat liver nuclei is the result of increased synthesis of the enzyme or a reduction in the amount of an endogenous ribonuclease inhibitor.

- 6223 FAILURE OF THE ANTIBODY METHOD TO DEMONSTRATE A CIRCULATING HORMONAL FACTOR AFTER PARTIAL HEPATECTOMY. (E.) Hyde, T. A. (U. Liverpool, England), L. J. Hipkin and J. C. Davis. Nature (London) 209(5027):1034-1035, 1966.

Adult male Wistar rats were subjected to 65% partial hepatectomy; 24 hr. later, when mitotic activity in the liver is just beginning, blood was obtained from either the aorta or the portal vein. Rabbits were immunized with these sera mixed with Freund's adjuvant. The effect of the antisera was tested in rats and mice which had been subjected to partial hepatectomy 48 hr. previously. Mice received 2 ml, rats 4 ml of the adsorbed antiserum. When mitoses were counted and the amount of regeneration (on a wet basis) was determined, it was seen that the antisera had no significant effect compared to inj. of saline, no inj., or of normal sera. In rats, there actually was a very slight rise in the mitotic rate.

- 6224 GLUCOSE-1-PHOSPHATE URIDYLYL TRANSFERASE ACTIVITY IN DEVELOPING RAT LIVER. (E.) Hsia, Y. E. (Yale U. Sch. Med., New Haven, Conn.) and I. K. Brandt. Yale J. Biol. Med. 38(4):374-380, 1966.

Glucose-1-phosphate uridylyl transferase activity was assayed in the soluble fraction of rat liver in animals ranging from fetal day 18 to adults. The activity (micro-moles/min. per g liver) in adult males was 82, in females it was 66; this sex difference was significant. On fetal day 18 activity was 12% of that of the adult male but rose rapidly thereafter. Maximal activity was found during the first 2 hr. after birth: 98. From the second day to weaning, enzyme activity was not significantly different from that of the adult female. The sex difference in adults and the postnatal peak, both significant statistically, have not been noted previously.

- 6225 STUDIES ON BILIRUBIN SULPHATE. (E.) Noir, B. A. (Nat. Inst. Health, Haedo, Argentina), R. J. Groszman and A. T. De Walz. Biochim. Biophys. Acta 117(2):297-304, 1966.

Synthetic bilirubin sulfate was prepared by the technic of Watson from bilirubin.

HEPATIC METABOLISM

Purification of the product obtained by treatment of bilirubin with the Liebermann-Burchard reaction was achieved by paper chromatography. The solvent system employed had previously been used for the separation of bilirubin and biliverdin and their resp. mono- and diglucuronides. The pigment obtained was not very sensitive to light, it was quickly oxidized at an acid pH, and was very stable to alkali. It had a max. absorption at 455 millimicrons in aqueous soln. at pH 7 and its fluorescence and behavior on oxidation, reduction and diazotization indicated that the bilirubin moiety of the molecule was unaltered. It has been shown that, in addition to bilirubin glucuronides, bilirubin is excreted in human bile as a disulfate derivative.

- 6226 LIPOTROPIC EFFECT OF COLD ON RAT LIVER. (E.) Bobek, P. (Inst. Human Nutr. Res., Bratislava, Czech.) and E. Ginter. Nature (London) 210(5032): 204, 1966.

Male Wistar stock rats were fed ad libitum a high fat-cholesterol diet for 7-13 wk. and maintained at 22°C; one group was exposed to 2°C for 8 hr. of each day. In controls kept at room temperature, the high fat-cholesterol diet resulted in a significant increase in conc. of esterified fatty acids in the liver and a marked decrease in liver glycogen. This effect was not seen in the cold-acclimatized group; in these rats values were nearly the same as those of rats fed the control Larsen diet. Biosynthesis of fatty acids from 1-C¹⁴-acetate in the liver was lowered in the group exposed to cold. In the group of animals exposed to cold increased mobilization of fatty acids from reserve tissues was found and a simultaneous decrease was observed in the conc. of liver fatty acids.

- 6227 INCORPORATION OF STEARATE-1-C¹⁴ AND OLEATE-1-C¹⁴ INTO PHOSPHATIDYL CHOLINE AND PHOSPHATIDYL ETHANOLAMINE OF RAT LIVER MITOCHONDRIA. (E.) Morin, R. J. (Los Angeles Co. Harbor Gen. Hosp., Cal.). Life Sci. 5(7): 649-653, 1966.

Groups of rats maintained on a synthetic fat-free diet or the same diet supplemented with 3% cholesterol for 6 wk. received intragastrically either sodium 1-C¹⁴-stearate or sodium 1-C¹⁴-oleate 1, 2, 4, and 24 hr. before sacrifice. Liver mitochondria were isolated by the method of Hogeboom and subjected to analysis. The specific activities of phosphatidyl choline on all diets and at all time intervals were higher than the activities of phosphatidyl ethanolamine in the corresponding groups, with the exception of the 24-hr. activities in both the groups that received oleate. At all time intervals after admin. of the isotopes, the groups given stearate had a higher specific activity in both phosphatidyl choline and phosphatidyl ethanolamine than the corresponding groups given oleate; also at 24 hr., the specific activities of both phospholipids in the stearate group without cholesterol were higher than at 4 hr., whereas the 4- and 24-hr. activities were not significantly different in the oleate admin. group (without cholesterol). Cholesterol feeding resulted in higher 4 hr. activities in both phospholipids in the group given stearate, as compared to the group given stearate without cholesterol. In the cholesterol plus oleate group, however, the 4-hr. specific activities were not affected, but the 24-hr. activities were considerably lower for both phospholipids as compared to the non-cholesterol group.

- 6228 DRUG INTERACTION WITH HEPATIC MICROSOMAL CYTOCHROME. (E.) Remmer, H. (U. Pennsylvania, Philadelphia), J. Schenkman, R. W. Estabrook, H. Sasame, J. Gillette, S. Narasimulu, D. Y. Cooper and O. Rosenthal. Molec. Pharmacol. 2(2):187-190, 1966.

The addition to rat liver microsomes of various substrates caused two types of spectral changes. One group of compounds, such as hexobarbital, phenobarbital, aminopyrine, and amobarbital, caused the appearance of a trough at about 420 mμ and the simultaneous appearance of an absorption band at about 385 mμ. In the

HEPATIC METABOLISM

presence of excess reduced triphosphopyridine nucleotide, the trough was intensified and shifted slightly to about 423 m μ . The second type of spectral change was obtained on addition of a substrate such as aniline or 2,4-dichloro-6-phenylphenoxyethylamine HCl. In this case an absorption band appeared at about 430 m μ with the concomitant disappearance of an absorption band at about 390 m μ . In the presence of reduced triphosphopyridine nucleotide the absorption peak obtained with aniline was frequently shifted to 435 m μ . On the basis of these observations, two hypotheses are suggested to explain the interaction of substrates with the liver microsomal mixed function oxidase system.

- 6229 STUDIES OF INTERACTIONS OF 3,4-BENZPYRENE, 3-METHYLCHOLANTHRENE, CHLORDANE, AND METHYLTESTOSTERONE AS STIMULATORS OF HEPATIC MICROSOMAL ENZYME SYSTEMS IN THE RAT. (E.) Mullen, J. O. (U. Iowa, Iowa City), M. R. Juchau and J. R. Fouts. *Biochem. Pharmacol.* 15(2):137-144, 1966.

3,4-Benzpyrene, 20-methylcholanthrene, and chlordane all stimulate the hepatic microsomal enzymes, benzpyrene and zoxazolamine hydroxylases, reduced nicotinamide adenine dinucleotide phosphate oxidase, and the amount of CO-binding pigment in adult male Long-Evans rats. Of the 3 compounds, chlordane is most active with reference to nitro reductase, the oxidase, and CO-binding pigment; only chlordane stimulates nitro reductase. Benzpyrene and methylcholanthrene stimulate benzpyrene hydroxylase three-fold. The stimulatory effects of benzpyrene or methylcholanthrene, and chlordane upon zoxazolamine hydroxylase and CO-binding pigment are additive when chlordane is given with either methylcholanthrene or benzpyrene to the same animal, indicating that chlordane may stimulate the activity of these enzymes by mechanisms different from benzpyrene or methylcholanthrene. Such additive effects are not seen with benzpyrene hydroxylase or the dinucleotide phosphate oxidase activity. Chlordane and methyltestosterone stimulate liver microsomal aminopyrine N-demethylase activity of adult females. No additive effects are seen when the two compounds are given together to the same animal, indicating that these two compounds may stimulate this drug metabolizing pathway by similar mechanisms.

- 6230 THE EFFECTS OF ADRENALECTOMY AND HYDROCORTISONE ON RAT LIVER METABOLITES AND GLYCOGEN SYNTHETASE ACTIVITY. (E.) Hornbrook, K. R. (Washington U. Sch. Med., St. Louis, Mo.), H. B. Burch and O. H. Lowry. *Molec. Pharmacol.* 2(2):106-116, 1966.

In *in vitro* studies of glycogen metabolism in rat liver, the levels of 12 metabolites believed to be associated with the pathway from lactate to glycogen were studied, and results indicate that the major defect in synthesis following adrenalectomy occurs at the step between uridine diphosphate-glucose and glycogen. This was confirmed by attempts to induce glycogen formation with lactate admin. When glycogenesis was restored with cortisol the changes in metabolite levels indicated that the uridine diphosphate-glucose to glycogen step was greatly facilitated. *In vitro* measurements of hepatic glycogen synthetase activities, together with kinetic studies of the enzyme, showed that adrenalectomy does not lower the total synthetase level, but causes a conversion of most of the enzyme to the form that is dependent on glucose-6-phosphate for activity. Cortisol, conversely, does not significantly change the total synthetase level but converts a substantial amount of the glucose-6-phosphate dependent synthetase to the "independent" form. It is concluded that glucocorticoids permit glycogen synthesis by maintaining part of the glycogen synthetase in the form which is active even at low glucose-6-phosphate levels.

- 6231 XANTHINE OXIDASE FROM LIVER AND DUODENUM OF THE RAT: HISTOCHEMICAL LOCALIZATION AND ELECTROPHORETIC HETEROGENEITY. (E.) Sackler, M. L. (Cornell U. Med. Coll., New York, N. Y.). *J. Histochem. Cytochem.* 14(4): 326-333, 1966.

Comparative investigation of xanthine oxidase activity in rat liver and duodenum specimens obtained from Carworth female rats was carried out by various technics.

HEPATIC METABOLISM

With the histochemical method employed, reaction product could be demonstrated in the epithelial cells of duodenal villi in glutaraldehyde-fixed cryostat sections incubated in 0.2 M sodium phosphate buffer at pH 7.4 containing 2.5×10^{-3} M hypoxanthine and 1 mg/ml nitro-blue tetrazolium (Nitro-BT). No reaction product was observed in similarly treated rat liver sections. However, when a microfluorimetric method using 2-amino-4-hydroxy pteridine as a substrate was employed, both liver and duodenal homogenates showed high enzyme activity. Upon fractionation of these homogenates, enzyme activity was present only in the high speed supernatant fraction. This fraction was also studied by zone electrophoresis on vertical starch gel and by acrylamide gel disc electrophoresis. Electrophoretic separation of xanthine oxidase into 2 bands was obtained along with its localization by incubation of the gels in the same medium as that described for the histochemical method. The duodenal enzyme showed a more rapid mobility than did the liver enzyme. The inability to demonstrate the liver enzyme histochemically is believed to depend on the lower hepatic conc. of the enzyme as compared to its duodenal conc.

- 6232 VARIATIONS IN SERUM TRANSAMINASE LEVELS IN ANIMALS INTOXICATED WITH TRICHLOROETHYLENE. (Fr.) Viallier, J. (Pasteur Inst., Lyon, France) and F. Casanova. C. R. Soc. Biol. (Paris) 159(11):2219-2221, 1965.

Serum glutamic oxalacetic transaminase and glutamic pyruvic transaminase levels were determined in rats after repeated inhalations (approx. 20 trials of 20-30 min. each) of trichloroethylene. Although oxalacetic transaminase levels were usually moderately elevated, results were transitory and variable; higher levels were usually found when determination was performed shortly after the last inhalation. Variations in pyruvic transaminase levels were less frequent. Similar experiments in rabbits showed rare abnormal levels of either glutamic oxalacetic or pyruvic transaminases. In rats fed trichloroethylene (11-18 doses of 0.17-0.21 ml each) by stomach tube, marked elevation of both transaminase levels was observed in animals fed for longer periods or in those sacrificed shortly after the final feeding.

- 6233 ATTEMPT TO ASSESS CHANGES OF LIVER FUNCTION IN RELATION TO AGE AFTER A PELENTAN LOAD. (Cz.) Nerad, V. (Charles U. Sch. Med., Prague, Czech.), L. Chrobak, V. Skaunic and V. Hassmanova. Cesk. Gastroent. Vyz. 20(1):13-16, 1966.

Liver function was assayed in a group of patients with no apparent hepatic or gastrointestinal disease which included 34 men between 19-47 yr. old (av. 36.5 yr.) and 33 men between 48-75 yr. old (av. 57.8 yr.). Thromboplastin time (Quick method), Factors II, V, X, Complex Factor VII, and Antithrombins II and III were determined before, and 24 hr. after, the admin. of 0.6 g of ethyl biscoumacetate (Pelentan; route not specified). The av. levels of vitamin K-dependent factors were usually lower in the older group; after the admin. of Pelentan, however, the decrease in the factor levels was more marked in the younger group.

- 6234 RELATIVE STORAGE CAPACITY AND MAXIMAL SECRETION RATE OF THE LIVER FOR SULFOBROMOPHTHALEIN IN RELATION TO AGE. (Cz.) Skaunic, V. (Charles U., Hradci Kralove, Czech.), V. Nerad and J. Jadrná. Cesk. Gastroent. Vyz. 19(8):523-532, 1965.

Ten men aged 18-47 yrs. (av. 32.8 yr.) and 10 men aged 53-69 yr. (av. 60.5 yr.) with no apparent liver disease (normal laboratory tests) were examined after the admin. of sulfobromophthalein (BSP) according to a method described by Wheeler et al. The av. relative storage capacity of the liver for BSP was 63.95 mg/mg% in the younger group and 38.8 mg/mg% in the older group. This difference was highly significant. Reduced liver volume and reduced endocrine secretion in the older age group may be associated with this phenomenon. The av. max. secretion rate of the liver for BSP was 8.77 mg/min. in the younger group and 8.32 mg/min. in the older group (insignificant difference). It is possible that the max. secretion rate tends to decline at a more advanced age than was investigated in this study.

HEPATIC METABOLISM

In general, the individual values for relative storage capacity and max. secretion of BSP were distributed over a wider range in the younger group, whereas in the older age group they tended towards lower and less variable limits.

- 6235 EFFECT OF SPARTEINE ON BILE EXCRETION OF BSP IN GUINEA PIGS AND RABBITS. (Fr.) Delphaut, J. (U. Marseille Sch. Med. Pharm., France) and M. Lanza. C. R. Soc. Biol. (Paris) 159(10):1996-1998, 1965.

The effect on sulfobromophthalein bile excretion of single (10 mg/kg i.v. 10 min. before inj. of dye) or repeated (9 inj. of 10-20 mg/kg s.c. before inj. of dye) inj. of sparteine sulfate was studied in guinea pigs and rabbits. Rate of bile excretion of sulfobromophthalein was the same in both treated groups and untreated controls. In guinea pigs, dye excretion was 68% in controls, 64% after single inj., and 66% after repeated inj. of sparteine; corresponding values in rabbits were 62, 59, and 61%, resp. No significant differences in choleresis were observed in controls or treated animals. Results indicate that sparteine has no toxic effect on the liver.

- 6236 ON THE METABOLISM OF LITHOCHOLIC ACID IN CHICKEN AND RABBIT. BILE ACIDS AND STEROIDS 167. (E.) Johansson, G. (Karolinska Inst., Stockholm, Sweden). Acta Chem. Scand. 20(1):240-244, 1966.

The metabolism of lithocholic acid- ^{14}C was studied in chickens and rabbits with bile fistulas after i.v. inj. of the sodium salt of the acid dissolved in saline. After inj. of 3 μC of lithocholic acid, 50% of the admin. isotope was excreted in the first 2 hr. bile portion in chickens; 20% more was excreted within the next 2 hr. Chromatography revealed that 5-10% of the acid was transformed into more polar products, mainly 3 α ,6 β -dihydroxy-5 β -cholanoic acid, while the remainder was excreted as unchanged lithocholic acid. In rabbits, after inj. of 8 μC of acid, 70% of the admin. isotope was excreted in the first hr. bile portion; 20% more was excreted during the next 3 hr. However, in rabbits, no conversion into more polar products was observed and lithocholic acid was excreted unchanged in the bile. The low extent of hydroxylation of lithocholic acid in chickens and rabbits supports the hypothesis that the degree of cirrhogenic and pyrogenic effects of lithocholic acid is correlated with the capacity of the liver to metabolize lithocholic acid into more polar products.

- 6237 THE EFFECT OF LOWERED ENVIRONMENTAL TEMPERATURE ON LIPID METABOLISM IN RATS FED ON NORMAL AND HIGH-FAT, HIGH-CHOLESTEROL DIETS. (E.) Bobek, P. (Inst. Human Nutr. Res., Bratislava, Czech.) and E. Ginter. Brit. J. Nutr. 20(1):61-68, 1966.

Groups of adult, male Wistar rats were maintained on a nutritionally well-balanced diet. A group exposed to 2°C temperature for 8 hr. of each day showed a retardation of growth during the first wk. These cold-acclimatized rats showed a decrease in the conc. of esterified fatty acids in blood serum, liver and epididymal fat tissue. The hepatic synthesis of fatty acids from 1- ^{14}C -acetate remained unchanged. There was a decrease in conc. of cholesterol in blood serum, liver and lungs of rats exposed to cold. When a high-fat, high-cholesterol diet was given, exposure to cold increased the mobilization of lipids. In rats given the high fat diet the lipotropic action of cold on the liver was confirmed. This action was characterized by a decrease of esterified fatty acid levels and by an increase of glycogen conc. in the liver. This effect is probably due to a lowering of hepatic lipogenesis and to increased oxidation of fatty acids in the liver tissue.

- 6238 RELATION BETWEEN GLUCOCORTICOID LEVEL AND HEPATIC GLUTAMIC DEHYDROGENASE ACTIVITY. (E.) Nishikawara, M. T. (Ohio State U., Columbus) and J. G. Bricker. Am. J. Physiol. 210(3):586-590, 1966.

In rats, significant elevations in hepatic glutamic dehydrogenase activity resulted from daily inj. of 2 or 5 mg of cortisol. While 2 mg of cortisol per day induced

HEPATIC METABOLISM

elevations which were maintained for 7 days, the 5 mg dose stimulated a rapid increase for 48 hr. but by day 7 the activity had decreased to control levels. Adrenalectomy resulted in a significant decrease in the dehydrogenase activity. Daily cortisol (1 mg) admin. to adrenalectomized rats not only prevented this decrease but induced activities significantly higher than in sham-operated controls. Equimolar amounts of corticosterone, cortisol, and triamcinolone had quantitatively similar effects. Deoxycorticosterone was ineffective. The observed relationship between the glucocorticoid level and hepatic glutamic dehydrogenase activity suggests that the oxidative deamination of glutamate may be of major importance in catabolic conditions leading to gluconeogenesis and increased formation of urea.

- 6239 STUDIES ON THE BLOOD OF ANIMALS WITH REGENERATING LIVER. I. PERFUSION OF ISOLATED RAT LIVER WITH BLOOD FROM PARTIALLY HEPATECTOMIZED ANIMALS. (It.) Mangiantini, M. (U. Rome), A. Trentalance and N. Tarsia. Boll. Chimicofarm. 104(12):803-811, 1965.

The RNA and DNA content of the liver was studied in Sprague-Dawley rats under various experimental conditions. Rats subjected to partial hepatectomy (Higgins-Anderson technic) and sacrificed 72-336 hr. later showed an increase in RNA (Ceriotti method) and DNA (Burton method) content 3 days after hepatectomy which did not change significantly as the time after hepatectomy increased. The RNA content of normal rat liver perfused with blood from intact rats was not increased, while that perfused with blood from partially hepatectomized rats was increased. The addition of uridine (5 mg/ml of perfusion liquid) caused further and marked increase in RNA content in liver perfused with blood from hepatectomized animals but had no effect on the RNA content in liver perfused with blood from intact animals.

- 6240 IONIC COMMUNICATION BETWEEN LIVER CELLS. (E.) Penn, R. D. (Columbia U. Coll. Phys. Surg., New York, N. Y.). J. Cell Biol. 29(1):171-174, 1966.

In a study of free ionic flow between cells, mouse liver cells (both *in vitro* and *in vivo*) were impaled with KCl-filled microelectrodes. One microelectrode passed rectangular current pulses between the inside of the cell system and the outside bath soln. One or 2 other intracellular microelectrodes recorded the resulting resistive voltage drops across the cell membranes at various distances from the current electrode. In a typical experiment in which current ranging from $0.1-6 \times 10^{-7}$ amp was passed from the inside to the outside of the cell, the resulting changes in membrane voltage were measured by microelectrodes placed in cells 8.3 and 33 microns away from the current-passing microelectrode. The voltages are almost equal in the 2 cells for any given current. Thus, the resistance from the interior of one cell to that of the next must be low compared with the resistance of the liver surface. This ionic connection was found between cells in all directions throughout the liver.

- 6241 ON THE PROBLEM OF MATHEMATICAL MODEL OF SULFOBROMOPHTHALEIN KINETICS IN ORGANISM. (E.) Mikulecký, M. (Comenius U., Bratislava, Czech.). Acta Hepatosplen. (Stuttgart) 13(1):28-38, 1966.

A mathematical model is presented which attempts to describe the kinetics of sulfo-bromophthalein in the body after a single i.v. inj. This model attempts to take into account all possible pathways of transport of the agent: movement into and out of the liver cell into the Kupffer cell or blood, movement in the lymphatic circulation of the liver, bile ducts, other parts of the gastrointestinal tract, and uptake in other tissues. Data obtained by single inj. of sulfo-bromophthalein in dogs formed the basis for construction of the mathematical model. Formulas are presented for the relative storage capacity of the cells for agent and for the proper uptake function of liver cells. The secretory function of liver cell is defined both by the exponential rate of dye secretion into the bile (for which a formula is offered), and by the secretory transport maximum (T_m) which is covered by another formula. Calculations were carried out on a digital computer. Results

HEPATIC METABOLISM

obtained in this way are in approximate agreement with the results obtained by the infusion methods.

- 6242 THE MICELLAR PROPERTIES OF BILE. (E.) DePalma, R. G. (2065 Adelbert Rd., Cleveland, Ohio), C. A. Hubay and S. Levey. J.A.M.A. 195(11):943-945, 1966.

The surface activity, specific gravity, osmolality, and arborization patterns of normal human bile were determined. The av. surface tension of gallbladder bile and hepatic bile obtained by drainage of the common bile duct was about the same (av. 42.0 and 42.6 dynes/cm, resp.). Bile obtained from the common duct of 1 patient following conversion of the sphincter of Oddi and T-tube drainage of the common bile duct, had a surface activity within normal limits (40.9 dynes/cm) just after surgery, but later its surface activity fell to 29.8-31.9 dynes/cm, corresponding to a specific gravity of 0.999-1.006. This suggested either interaction of hepatic bile with the duodenal fluid, or an effect of drainage of the common duct upon hepatic bile composition. Both gallbladder and hepatic bile were uniformly isotonic with serum, as osmolality studies indicated. Hepatic bile showed the arborization phenomenon, but untreated gallbladder bile did not. The arborization phenomenon disappeared when common bile duct bile was dialyzed. Addition of excess sodium chloride to gallbladder bile resulted in a coarse but similar arborization pattern, but the pattern was absent at chloride conc. up to 61.8 mEq/1000 ml. There was no relationship between the character of the pattern and the presence or absence of cholelithiasis.

- 6243 A STUDY OF HEPATIC CARBONIC ANHYDRASE. (E.) Maren, T. H. (U. Florida Coll. Med., Gainesville), A. C. Ellison, S. K. Fellner and W. B. Graham. Molec. Pharmacol. 2(2):144-157, 1966.

Holtzman rats and mongrel dogs were prepared with cannulas into the common duct; in dogs the cystic duct was first ligated. Dog and rat liver contain carbonic anhydrase in supernatant and particulate fractions. Hepatic bile of both species has higher HCO_3^- and lower Cl^- conc. than plasma. The enzyme in all fractions of dog liver was inhibited by unsubstituted aromatic sulfonamides at conc. of 10^{-6} to 10^{-9} M. When these drugs were admin. i.v. at doses which yield more than 99% enzyme inhibition, they lowered biliary HCO_3^- and raised biliary Cl^- conc. Certain of the drugs were secreted by liver and conc. in the bile of both species. Rat liver supernatant carbonic anhydrase was nearly refractory to sulfonamide inhibition in vitro; this is the first example of such lowered response in the animal kingdom. Biliary electrolytes in the rat were accordingly not altered by high doses of these sulfonamides.

- 6244 EFFECT OF EXPERIMENTAL BILIARY OBSTRUCTION ON THE JUXTAGLOMERULAR APPARATUS, PERIPHERAL PLASMA ALDOSTERONE, AND ASCITES. (E.) Gliedman, M. L. (State U. New York, Brooklyn), R. I. Ryzoff, J. F. Mullane, B. Lerner, L. Fox and K. E. Karlson. Am. J. Surg. 111(1):138-146, 1966.

Biliary obstruction was produced in dogs by either division or ligation (single or double) of the common bile duct. Ligation of the bile duct produced only transient abnormalities of liver function. After bile duct division, free and wedged hepatic vein pressure and inferior vena cava pressure below the liver tended to increase; inferior vena cava pressure above the liver remained unchanged. All pressures remained normal after bile duct ligation. The juxtaglomerular index (obtained by Hartroft's method) was 2.7 in normal dogs, 8.9 after bile ligation, and 35.8 after division of the bile duct. The av. peripheral blood aldosterone values in normal dogs were 13 mg%. After bile duct division, 5 of 15 animals showed about double this blood aldosterone value and also developed massive ascites; another showed massive ascites without elevated blood aldosterone; the others showed normal blood aldosterone levels with moderate (5) or no (4) ascites. Significant correlations were seen between peripheral blood aldosterone levels and abdominal inferior

HEPATIC METABOLISM

vena cava pressure, serum potassium, and hepatic vein pressures. Serum sodium tended to decrease, but not significantly, when blood aldosterone was increased. Ascites was produced by bile duct ligation in only 1 animal. Dogs with ascites showed elevated inferior vena cava and hepatic vein (wedged or free) pressures, elevated aldosterone and potassium levels, slightly decreased serum albumin, low serum sodium, and/or an elevated juxtaglomerular index; individual animals did not show all of these features, however. It is suggested that the liver may affect the kidney by the inferior vena cava, by hepatic congestion, or by release of an aldosterone stimulus resulting in hepatocellular damage.

- 6245 THE PROPORTIONS OF DIFFERENT LECITHINS IN THE LIVERS OF RATS DEFICIENT IN ESSENTIAL FATTY ACIDS. (E.) Collins, F. D. (U. Melbourne, Victoria, Australia). Biochem. J. 99(1):117-122, 1966.

Lecithin was prepared from the livers of rats which had been maintained on a fat-free diet which minimized the number of fatty acids present and facilitated the study. Rats also received radioactive phosphate (H_3PO_4). Analysis was by means of counter-current distribution. Thin-layer chromatography showed that only lecithin was present. The distributions of phosphorus and the fatty acids at the 3 and 2 positions were determined. It was shown that 26% of the fatty acids in the 3 position were unsaturated and that most of the $\Delta^{5,8,11}$ -eicosatrienoic acid and arachidonic acids occurred as the stearyl or oleoyl lecithins.

- 6246 WATER CONTENT AND METABOLIC ACTIVITY OF MITOCHONDRIA FROM FETAL RAT LIVER. (E.) Williams, M. L. (U. Pennsylvania, Philadelphia). Biochim. Biophys. Acta 118(2):221-229, 1966.

Mitochondria were prepared from the liver of fetal rats usually after 19-21 days of gestation. These mitochondria showed marked spontaneous swelling in KCl-Tris suspension but not in sucrose. This spontaneous swelling was inhibited by the use of ethylenediaminetetraacetic acid in the preparation medium. Fetal mitochondria swelled much less in the presence of phosphate, thyroxine and calcium than do adult mitochondria but response to oxidized plus reduced glutathione was similar in fetal and adult preparations. Swollen fetal mitochondria contract well upon addition of ATP and magnesium except in the presence of phosphate. Fetal liver mitochondria oxidized succinate and glutamate-malate at rates equal to or higher than those of adult mitochondria. They are capable of carrying out active oxidative phosphorylation with good respiratory control. Fetal mitochondria showed marked lipid peroxidation on incubation without exogenous substrate. This peroxidation was inhibited by vitamin E.

- 6247 AN EXPERIMENTAL STUDY ON BILE EXCRETION IN REGENERATED LIVER. (E.) Kijima, K. (Kanazawa U. Sch. Med., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 35(2):224-252, 1966.

After cholecystectomy and preoperative collection of bile samples, dogs on a standard diet were subjected to about 50% hepatectomy. Hepatic bile was collected by means of a cannula into the choledochus for 1-2 hr. at various intervals after operation: 2 days, 1, 2 and 3 wk., and 1, 2 and 3 mo. Total hepatic bile at first decreased, then increased to 2.2 times the preoperative level after 2 mo. returning to normal at 3 mo. Total bile acids, bilirubin and phospholipid in bile decreased immediately after operation, rose to a high level after 2 mo. with return to normal after 3 mo. Total bile cholesterol decreased gradually after resection for 2 wk., then rose to 2.2 times the preoperative level after 2 mo. with return to normal after 3 mo. Both the sulfobromophthalein retention test and serum cholesterol-ester ratio indicated abnormal liver function after resection with return to normal 3-4 wk. after surgery. The icteric index, level of phospholipid and total cholesterol content indicated similar transient abnormal liver function. These studies indicate that after partial hepatectomy there is a period of temporary hyperfunction of the liver.

HEPATIC METABOLISM

- 6248 EXPERIMENTAL STUDIES ON ATTITUDE OF DOGS WITH REGENERATED LIVER AGAINST HEMORRHAGIC SHOCK. (E.) Tsuji, M. (Kanazawa U. Sch. Med., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 35(2):268-292, 1966.
Intact dogs and dogs which received 50% partial hepatectomy 2 mo. prior to experiment were subjected to hemorrhagic shock by 2 methods: that of Lamson and that of Wiggers. When shock was induced by Wiggers' method there was no significant difference in the two groups relative to 12 and 24 hr. survival. When shock was induced by the Lamson method, there were no significant differences in any of the parameters measured during various phases of reversible and irreversible shock. Portal pressure was higher in the hepatectomized group before the withdrawal of blood, and the rate of recovery after the reinfusion of blood was a little faster than was seen in controls, suggesting a somewhat greater vascular resistance in the intrahepatic portal system. There were no significant differences relative to hematocrit.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

- 6258 A SUCTION-BIOPSY PROCEDURE FOR OBTAINING SPECIMENS OF MUCOSA FROM THE RIGHT AND LEFT COLON. (E.) Colagrande, C. (U. Rome), P. Arullani and C. Casale. Am. J. Dig. Dis. 11(5):389-393, 1966.
- A technic for biopsy of the colon involves passing transnasally a long polyvinyl tube weighted with a small bag of mercury distally and with a suction type capsule at the proximal end. When the distal end is passed anally gentle traction is employed until the capsule is in the proper position in the colon. Passage of the tube in different subjects requires 1-7 days, av. 3 days. The biopsy is carried out as usual with a syringe at the distal or anal end of the tubing. Among 25 trials with the Crosby-Kugler or Carey capsules, there were 4 biopsy failures. The procedure is attended by only minor discomfort. None of the patients experienced "postbiopsy syndrome".
- 6259 SITES OF IODIDE ENTRY INTO AND ABSORPTION FROM THE GUT LUMEN AND THEIR RELEVANCE TO THE RESIN--[¹³¹I] HUMAN SERUM ALBUMIN TECHNIQUE FOR INVESTIGATION OF PROTEIN-LOSING ENTEROPATHY. (E.) Scott, P. J. (Auckland Hosp., New Zealand), C. Tasman Jones and J. P. Simcock. Clin. Chim. Acta 13(3): 292-311, 1966.
- After i.v. admin. of 2 μ c of NaI¹³¹ to 2 subjects with intact thyroid function and 3 in whom thyroid iodide uptake had been blocked by admin. of Na¹²⁷I, the salivary/plasma-iodide levels were constant in all subjects for up to 24 hr. In normal subjects the gastric juice/plasma-radio-iodide ratios ranged from 15/1 to 65/1 (mean of 36/1) in 9 patients; in 4 who had received thyroid-blocking doses of I¹²⁷, mean ratio was 43/1. There was no correlation between salivary/plasma- and gastric juice/plasma-iodide ratios in a given person. While absolute amounts of iodide secreted varied with the flow rate on histamine stimulation, the gastric juice/plasma-iodide ratios remained constant for up to 4 hr. In patients with T-tube drainage of the choledochus, 9.3% of the radioactive dose admin. was recovered in a 24-hr. collection. After admin. of secretin to 2 patients (one of whom had received stable iodide) and to a patient with subacute fibrosing pancreatitis, all showed I¹³¹ in the pancreatic secretion. In dogs, there was an increase of iodine in the isolated segment of duodenum not receiving the pancreatic ducts after stimulation of flow by pancreozymin-secretin. In subjects who received i.v. either I¹³¹ or radio-iodinated protein, iodide was only recovered from the feces when a resin (IRA 400 Cl) was given. Results are also reported of one metabolic study in relation to a patient with protein-losing enteropathy.

GASTROINTESTINAL DISEASES

GENERAL

- 6290 REMOBILIZATION OF Entamoeba histolytica AFTER EXPOSURE TO IMMOBILIZING ANTIBODIES. (E.) Biagi, F. F. (U. Mexico Sch. Med., Mexico City), F. H. Beltran and P. S. Ortega. Exp. Parasit. 18(1):87-91, 1966.

Thirty min. after the fluorescent immune serum against E. histolytica trophozoites was placed in contact with motile trophozoites, approx. 90% were immobilized. Under the phase microscope the trophozoites appeared to be rounded and the cytoplasmic elements became more prominent. With UV light the fluorescence was seen on the surface; at 45 min. the fluorescence was regularly distributed in the ecto- and endoplasm. At 60 min. some nonfluorescent areas were noted in the cytoplasm. At 75 min. the fluorescent material was found in a vacuolate. At 90 min. the fluorescein diminished in intensity and was barely perceptible at 105 min. At this moment remobilization of the trophozoite was observed.

- 6291 EFFECT OF ALIMENTARY TRACT MICROORGANISMS ON THE DEVELOPMENT OF Trichinella spiralis IN MICE. II. (E.) Stefański, W. (Inst. Parasit., Polish Acad. Sci., Warsaw) and Z. Przyjalkowski. Exp. Parasit. 18(1):92-98, 1966.

Groups of male albino H mice (15-17 g) were fed muscle scraps containing 50 larvae of Trichinella spiralis. Just after inoculation, experimental mice received by mouth 24-hr. cultures of various organisms for 7 days. At sacrifice, the number of nematodes in the intestine was counted with the aid of a dissecting microscope. Compared to conventional mice the ingestion of Lactobacillus sp. led to a significantly reduced number of nematodes being found. Controls for the other groups were mice sterilized with neomycin. A significantly greater number of nematodes (compared to such controls) was found in mice given the following organisms by mouth: Escherichia coli, Proteus sp., Serratia marcescens, Arizona, Hafnia, and Pseudomonas aeruginosa.

- 6292 LIVE VACCINE IMMUNIZATION IN EXPERIMENTAL TYPHOID WITH A STREPTOMYCIN DEPENDENT STRAIN OF Salmonella enteritidis. (Jap.) Kishimoto, Y. (Keio U. Sch. Med., Tokyo). Nippon Saikingaku Zasshi (Jap. J. Bact.) 20(4):195-202, 1965.

In order to clarify the relationship between the effectiveness of immunization and the rate of multiplication or persistence of immunizing microorganisms in the host, a strain of streptomycin-dependent Salmonella enteritidis (8×10^4) was inj. i.p. into various groups of mice. Group 1 received 8 mg of streptomycin i.p. for 50 days; Group 2 received 8 mg for 12 days; Group 3 received no streptomycin, but Salmonella inj. were repeated 2 or 3 times during the immunization period. Homogenates of lymph nodes, spleen, liver, and remaining carcass (gastrointestinal tract excluded) were then cultivated on streptomycin-containing agar plates, and the number of viable bacteria was calculated. Some mice from each group were challenged i.p. with a dose of 8×10^3 of virulent S. enteritidis and mortality was observed for 21 days. In Group 1, the number of immunizing bacteria increased for 2 wk., then gradually decreased; a significant resistance to challenge with virulent organisms was also observed. In Group 2, the number of organisms also increased for 2 wk., but decreased rapidly thereafter and could not be detected in any of the homogenates at day 40 after immunization; acquired resistance to challenge was inferior to that of Group 1. In mice of Group 3, the number of immunizing bacteria decreased after every inj. and no resistance to challenge was observed.

- 6293 STUDIES ON DELAYED (CELLULAR) HYPERSENSITIVITY IN MICE INFECTED WITH Trichinella spiralis. III. SEROLOGIC AND HISTOPATHOLOGIC FINDINGS IN RECIPIENTS GIVEN PERITONEAL EXUDATE CELLS. (E.) Larsh, J. E., Jr. (U. North Carolina, Chapel Hill), G. J. Race, H. T. Goulson and N. F. Weatherly. J. Parasit. 52(1):146-156, 1966.

GENERAL

Twenty-one days before infection with Trichinella spiralis larvae (100 per mouse), a group of experimental Swiss mice received 1.5×10^6 peritoneal exudate cells from previously infected donors; a second group received the same vol. of cells prepared from non-infected donors; a third group was not pre-treated. Eleven days after infection the 12 experimental mice harbored significantly fewer adult worms (av. 52) than the 12 normal-cell controls (av. 74) and 12 untreated controls (av. 78). On the basis of serologic, and, especially, intestinal histopathologic findings, additional evidence is provided to support the hypothesis that worm elimination is associated with delayed hypersensitivity.

- 6294 DEVELOPMENT OF RESULTS FURNISHED BY THE BASOPHIL DEGRANULATION TEST IN THE COURSE OF EXPERIMENTAL IMMUNIZATION OF ANIMALS AGAINST ENTEROBACTERIA. (Fr.) Viallier, J. (Pasteur Inst., Lyon, France) and A. Sedallian. C. R. Soc. Biol. (Paris) 159(11):2217-2218, 1965.

The Shelley test (based on degranulation of basophils) was used to detect the presence of antibodies to Enterobacteriaceae in rabbits appropriately treated. In 3 rabbits inoc. s.c. with TAB vaccine, results were negative before and at the beginning of immunization; after a lapse of time, positive response was observed. Serological studies revealed a high titer of agglutinins for each of the bacteria in these animals. In 2 rabbits inoc. s.c. with a suspension of Escherichia coli 2686 killed by heating in a water bath for 1 hr. at 100°C, negative results were obtained both before and at the beginning of immunization; subsequently, results became positive, but irregularly so, and to a lesser degree than that seen in the previous group. Results were constantly negative in 33 tests conducted on the serum of a rabbit receiving no treatment. Results indicate that the Shelley test is a valuable means of detecting antibody-antigen reactions as long as the procedure is carefully controlled.

- 6295 APPENDICITIS IN ENTEROBIOSIS. (Rus.) Shubenko-Gabuzova, I. N. Med. Parazit. (Moskva) 34(5):563-566, 1965.

Examination of 2,443 appendices removed at operation revealed 433 with Oxyuris. Among 685 specimens which showed superficial or deep ulcerations with marked muscle destruction, hemorrhages, infiltrations with predominance of eosinophils, the parasites and their larvae were found in 411 cases. Among 746 cases with acute inflammatory processes, only 22 had Oxyuris. No parasites were found in 987 cases of chronic appendicitis and in 25 other cases (some with other changes). This infestation was three times as frequent in women as in men; it also affected chiefly young people (from age 10-18 yr.). Enterobiosis plays an important role in the pathogenesis of appendicitis. The mechanical, hemotoxic and neurotoxic effects of these helminths contribute to the establishment of secondary infections.

- 6296 DRUG RESISTANCE OF ENTEROPATHOGENIC AND NORMAL COLI BACTERIA. (Rus.) Shalman, S. L. (Petrograd Region. Inst. Sanit.-Hyg. Statistics, Leningrad, USSR). Antibiotiki 10(12):1097-1099, 1965.

Drug resistance of 1,092 strains of enteropathogenic coli bacteria and 214 strains of normal coli bacteria isolated from healthy children, adults and from 12 samples of river water was studied by use of paper disks and serial dilutions. The antibiotics tested were levomycetin [Chloromycetin], streptomycin, chlortetracycline, and mycerin (a neomycin-like antibiotic). No strains tested in 1959-61 were resistant to neomycin antibiotics. In 1962, 18.1% of serotype 0111 strains were resistant to neomycin; the resistant strains increased to 38.3% in 1963. Drug-resistant normal coli bacteria were isolated from 56.5% of 131 children, from 21% of adults, and from all samples of river water tested in 1962-63. Most strains of drug-resistant normal coli bacteria exhibited resistance to levomycetin, chlortetracycline, and sulfanilamides; in addition, most of the drug-resistant enteropathogenic coli bacteria were resistant to neomycin antibiotics.

GENERAL

- 6297 THE DURATION OF ANTIBIOTIC RESISTANCE BY Bacillus dysenteriae. (Rus.) Shershevksaia, R. S. (Khabarov Inst. Med., USSR). Antibiotiki 10(12): 1099-1102, 1965.

Studies were conducted for 5 yr. on 102 cultures of dysentery bacteria with induced adaptation and 56 strains isolated from dysentery patients and bacteria carriers resistant to levomycetin, streptomycin(s) and three tetracyclines. The sensitivity was determined by the procedure of serial dilutions on liquid media according to the bacteriostatic titer. The strains were maintained on semiliquid agar without antibiotics in sealed tubes and were transferred at the time of testing. Of 33 strains resistant to streptomycin, 16 remained resistant for 5 yr. Of 23 levomycetin-resistant strains, 5 remained resistant for the same period of time. The strains resistant to tetracyclines lost their resistance within 3 yr.; this fact makes tetracyclines promising from the standpoint of future potential use. No significant difference in the decrease of the resistance level was observed in Flexner and Sonne bacteria. Grigoriev-Shiga bacterial strains with induced adaptation proved to be sensitive after 15 mo. of storage to all antibiotics but streptomycin, to which the acquired resistance during the experiments was preserved.

- 6298 ROLE OF PENTAMETHYLENEDIAMINE (CADAVERINE) IN EXPERIMENTAL CHOLERA INFECTION. (E.) Veeraraghavan, N. (Pasteur Inst. S. India, Coonoor), V. Kalyanaraman and V. K. Visalakshi. Indian J. Med. Res. 54(2):117-128, 1966.

When an extract from monkey, mouse, guinea pig, and rabbit intestine was incubated with cultures of Vibrio cholerae, cadaverine (pentamethylenediamine) could be identified by chromatography of the material. Some cadaverine was found in cooked meat. The production of cadaverine from gastric mucin and its absence when intestinal extracts are prepared after completely scraping the mucosa, suggest the possibility that some of the enzyme systems of V. cholerae, such as mucinase, produced a suitable substrate for cadaverine production by acting upon the intestinal mucosa. Pathogenic strains of V. cholerae produced in vitro larger amounts of cadaverine than non-pathogenic strains. Addition of pyridoxal phosphate to the latter led to formation of cadaverine. Some cadaverine was produced by some other intestinal bacteria, especially those causing diarrhea. After experimental cholera infection, cadaverine was detected in intestinal fluids and diarrheal stools of guinea pigs and rabbits. Cadaverine by itself produced some symptoms of cholera, such as diarrhea and fluid loss. Cadaverine appeared to alter the intestinal wall rendering it permeable to the toxic products of V. cholerae.

- 6299 SOME ASPECTS OF LIPID METABOLISM IN ANOREXIA NERVOSA. (It.) Cravetto, C. A. (U. Turin, Italy) and L. Soranzo. Rass. Fisiopat. Clin. Ter. 37(5):333-354, 1965.

Plasma free fatty acid levels were determined (Dole method) after fasting for 39 hr. in 11 women (age 16-24 yr.) with anorexia nervosa and marked reduction of body wt. Results were compared to those of a group of normal, non-obese women (21-56 yr. old). At 39 hr., the increase in plasma free fatty acids was less pronounced in anorexia nervosa patients (621-1687 μ Eq/liter) than in normal women (750-2153 μ Eq/liter); blood glucose levels were also less increased in patients with anorexia nervosa (50-77 mg%) than in normal women (72-88 mg%). Following stimulation with epinephrine (0.1 μ g/kg/m²) for 20 min., anorexia nervosa patients showed a more marked and prolonged increase of plasma free fatty acids than normal patients did. Results seem to indicate a lesser need for energy sources on the part of tissues in anorexia nervosa.

- 6300 TREATMENT OF MASSIVE GASTRODUODENAL HEMORRHAGE (PORTAL HYPERTENSION EXCLUDED). Edelmann, G., P. Boutelier, J. Brenot and R. Schmitt. Med. Acad. Chir. (Paris) 92(10-11):304-315, 1966.

Results are reported for the treatment of 76 patients with massive gastroduodenal

GENERAL

hemorrhage due to chronic gastroduodenal ulcer (47), acute ulcer (8), gastritis (3), hiatus hernia (3), gastric cancer (6), or of unknown origin (9). In 13 patients hemorrhage resulted from lesions caused by cortisone (3), aspirin (4), a combination of cortisone and aspirin (2), phenylbutazone (2), or anticoagulant treatment (2). Emergency surgery during the bleeding period was performed in 33 patients, among whom 8 postoperative deaths were reported. Delayed surgery (2-60 days following cessation of bleeding) was performed in 19 patients; 18 cures and 1 death (pulmonary embolism) were reported. Of 24 patients not subjected to surgery, 19 had definite cessation of bleeding with no recurrence and 5 died from persistent or recurrent hemorrhage. Overall mortality was 14 of 76 patients, or 17%. Hemorrhage due to chronic gastroduodenal ulcer was treated by 2-step gastrectomy (27), degastrogastrectomy (3), and partial gastrectomy with vagotomy (3); duodenal fistula was the most frequent (17) complication in this group. Of 6 patients with hemorrhage due to acute ulcer, 4 were treated by simple hemostatic suture (3 of 4 cures) and 2 by gastrectomy (both cured). Hemorrhage due to gastritis was treated in 2 patients by gastrectomy (1 bled for 6-12 days after surgery and then ceased) while the other patient stopped bleeding after explorative gastrotomy.

6301 INFLAMMATION IN THE SALIVARY GLANDS. (E.) Waterhouse, J. P. (London Hosp. Coll. Med., London, E. 1). Brit. J. Oral Surg. 3(3):161-171, 1966. In a series of 248 autopsy cases, focal lymphocytic adenitis (foci of lymphocytes and histiocytes associated with apparent loss of parenchyma) in the absence of infection or cancer was observed very frequently upon microscopic examination of the parotid, submandibular, and lacrimal glands. Incidence was highest in women 45 yr. old and over and was higher than expected in patients who died with rheumatoid arthritis. Results suggest that the adenitis may be a focal form of Sjögren's syndrome, which has features of an autoimmune disease, including the presence in the serum of patients suffering from it of auto-antibodies to antigens present in certain of their tissues. A genetic predisposition is also indicated in these patients. The pathological basis of this salivary gland disease seems to be replacement of gland parenchyma by infiltration of lymphocytes and histiocytes and duct obstruction due to duct hyperplasia (Mikulicz's disease). Lymph nodes were constantly present within the parotid glands but rather infrequent in the submandibular glands.

6302 LYMPHORETICULOSARCOMA OF THE STOMACH AND INTESTINE. (Fr.) Ennuyer, A. (Curie Found., Paris) and P. Bataini. J. Radiol. Electr. 47(3-4): 163-175, 1966. Results of treatment are reported for 32 patients with lymphoreticulosarcoma of the gastrointestinal tract treated at the Curie Foundation from 1948-60. Regression of disease for 5 yr. or more was obtained in 8 of 14 patients with apparent primary lymphoreticulosarcoma; of these, regression lasted for 13 yr. in 3, 11 yr. in 2, 10 yr. in 1, and 8.5 yr. in 1, while 1 patient died after a regression of 8.5 yr. Five-yr. regression, postoperative mortality, and failure were observed in 3, 1, and 1, resp., of 5 cases localized in the stomach; 1, 1, and 1, resp., small intestine; 1, 0, and 1, resp., ileocecal region; 2, 0, and 0, resp., mesentery; 1, 0, and 1, resp., rectum. Treatment consisted of surgery alone (1 regression and 2 postoperative deaths); surgery and systemic postoperative radiotherapy (3 regressions and 1 failure); radiotherapy following incomplete surgery or recurrence (2 regressions and 1 failure); radiotherapy alone (2 regressions and 2 failures). Chemotherapy (usually nitrogen mustard) was admin. to 9 patients with generalized lymphoreticulosarcoma with gastrointestinal localization (all but 1 died within 9 mo. of gastrointestinal involvement) and 9 patients with metastatic lymphoreticulosarcoma of the gastrointestinal tract (death usually occurred 2-43 mo. after gastrointestinal involvement).

GENERAL

- 6303 DIGESTIVE TRACT LESIONS OF CHEMICAL ORIGIN, EXCLUDING HORMONES, ANTI-BIOTICS, AND ANTIMETABOLITES. (Fr.) Cabanne, F., R. Lambert, J. Feroldi and C. Klepping. *Laval Med.* 37(4):387-415, 1966.

Fifteen patients (11 men and 4 women; age 28-69 yr.) are reported with lesions of the digestive tract subsequent to habitual (11) or occasional (4) use of aspirin; of 12 patients with hematemesis, surgery was performed immediately after treatment in 5 and after 15-25 days of treatment in 7; of 3 patients with melena, surgery was required 7, 14, and 14 days after treatment. Besides acute (6) or subacute (9) gastritis and congestion of the mucosa and submucosa, 9 patients had a Cruveilhier ulcer of the lesser curvature (5), pyloric region (3), or greater curvature (1); 4 patients had 2 Cruveilhier ulcers in the region of the lesser curvature; 1 patient had an acute ulceration of the posterior wall of the stomach; 1 patient had an adenocarcinoma of the lesser curvature. Four other cases are reported in which digestive tract lesions occurred after the use of phenylbutazone, phenacetin, hexacycline, or cascara. Experimental studies with rats revealed the presence of gastrointestinal ulcerations in 8 of 20 following s.c. inj. of 150 mg/kg of phenylbutazone; 2 of 10 after 200 mg/kg; 5 of 10 after 100 mg/kg. Among 40 rats treated with acetylsalicylic acid, gastrointestinal ulcerations occurred in 7 of 10 following s.c. inj. of 5,000 mg/kg for 5 days; in 8 of 10 following 500 mg/kg p.o. for 7 days; in 5 of 10 after 600 mg/kg p.o. for 7 days; in 8 of 10 following 600 mg/kg p.o. for 5 days. Other lesions in all groups included atrophy and edematous or erosive inflammation of the stomach or small intestine. Among 10 rats treated with 50 mg/kg s.c. of reserpine for 5 days, ulcerations of the stomach or glandular mucosa appeared in 8 and 1 animals, resp.; glandular mucosa was normal in 9 of 10 and pyloric region was normal in all 10 animals. Various pathogenetic explanations are included.

- 6304 DIGESTIVE TRACT ALTERATIONS SECONDARY TO TREATMENT OF THE CENTRAL AND AUTONOMIC NERVOUS SYSTEMS. (Fr.) Potet, F. (Bichat Hosp., Paris), E. Martin, C. Vedrenne, Hanau, C. Caulin, J. P. Ferrier and S. Bonfils. *Laval Med.* 37(4):435-458, 1966.

Of 420 autopsies of patients subjected to neurosurgery, 25.4% had lesions of the digestive tract. Lesions were most frequent in the stomach (hemorrhagic and ulcerative lesions) and duodenum (necrotizing and perforating ulcers and fibrinous exudation) and were accompanied by marked venous dilatation and congestion. Esophageal lesions were rare; dilatation of the small intestine and colon was seen in 25% of cases. Lesions were more frequent in males, probably because of higher incidence of ulcer. Digestive tract complications occurred with greater frequency 1-8 days (68 patients) or 13 days (30 patients) after surgery. Among 196 cases, most frequent cause of digestive tract lesions was glioma (40.5%), hematoma or abscess (17.8%), and metastases (14%). No correlation was found between localization and type of neurological lesion and localization and type of digestive tract complication. The case is reported of a 37-year-old man who had been treated for schizophrenia with various neuroleptic agents (Haloperidol, Largactil, and others) and who presented with marked abdominal swelling and cardiovascular collapse; gastrectomy was performed and histological examination revealed hemorrhagic infarction and necrosis of the mucosa of the stomach and first portion of the duodenum. Although results of experiments using Wistar rats are incomplete, the authors report the finding of diffuse hemorrhage of the stomach and intestine (with no mucosal changes) in 50% of animals subjected to bilateral electrocoagulation of the frontal region.

- 6305 CHROMATOGRAPHIC (SEPHADEX) ISOLATION OF A GASTRIC SECRETAGOGUE FACTOR IN THE URINE OF PATIENTS WITH THE ZOLLINGER-ELLISON SYNDROME. (Fr.) Vatie, J. (Bichat Hosp., Paris), S. Bonfils, J.-P. Bader, M. Dubrasquet and P. Laudat. *Path. Biol. (Paris)* 14(5-6):358-361, 1966.
- Chromatographic (Sephadex Gel 25) studies were conducted on urine extracts obtained from 3 patients (2 women and 1 man; age 35-59 yr.) with the Zollinger-Ellison

GENERAL

syndrome. Preliminary studies showed that the major part of gastric secretagogue activity was situated in a fraction whose coefficient of elution lies between 2.70 and 2.86. Purification of this fraction by repeated passage on smaller columns showed a peak at which all biological activity is concentrated and a constant elution coefficient using a standardized column. A molecular wt. of 1,800 was calculated. The method of preparation of the urine extract, its UV absorption at 280 millimicrons, and its low molecular wt. indicate that the gastric secretagogue factor in the urine of patients with the Zollinger-Ellison syndrome is a polypeptide.

6306 MECHANISM OF THE ZOLLINGER-ELLISON SYNDROME. (Ger.) Becker, V. (Cent. Hosp., Karlsruhe, Germany). *Klin. Wschr.* 44(7):370-375, 1966.
Examination of the pancreas of 5 patients who died of complications of gastric or duodenal ulcers showed hyperplasia of the "insular duct organs" in 1 patient, islet cell adenomas in 4 patients (associated in 1 patient with islet hyperplasia and scar-forming pancreatitis), and an unsuspected islet cell carcinoma in 1 patient. Three of these patients were included in a group of 16 fatal ulcer cases seen over a 1-yr. period. Histochemical staining of the adenomas failed to demonstrate gastrin or insulin; the adenomas also seemed to contain no A cells. The adenomas were histologically very similar to small intestinal carcinoids, which belong to the clear cell series of tumors. It is concluded that the Zollinger-Ellison adenoma arises in the "insular duct organs" and contains a pathological excess of secretin-producing cells with a gastrin-stimulating physiological effect. This would account for the increase in gastric acidity and the frequency of ulcer formation in the Zollinger-Ellison syndrome. A feedback mechanism between the stomach and the pancreas is suggested.

6307 CARCINOGENIC EFFECTS OF INTRAGASTRIC 3-METHYLCHOLANTHRENE AND 7,12-DI-METHYLBENZ(a)ANTHRACENE IN WISTAR AND SPRAGUE-DAWLEY RATS. (E.) Gruenstein, M. (Temple U. Sch. Med., Philadelphia, Pa.), D. R. Meranze, D. Thatcher and M. B. Shimkin. *J. Nat. Cancer Inst.* 36(3):483-502, 1966.
After repeated intragastric admin. of 20-methylcholanthrene or single intragastric instillations of 9,10-dimethyl-1,2-benzanthracene, mammary carcinomas appeared in a higher proportion and earlier in Sprague-Dawley than in Wistar rats (total in 2 experiments, 384). Fibroadenomas of the breast were seen in 20% of Sprague-Dawley rats by 36 wk. In Wistar rats observed for 1 yr. after dimethylbenzanthracene admin., fibroadenomas occurred in 64% and adenosis in 49%; after methylcholanthrene, these reactions occurred in less than 10%. Intraluminal secretion indicative of lactation was noted in approx. 20% of fibroadenomas and adenoses. Nine Wistar rats developed lymphoma: 5 after dimethylbenzanthracene and 4 after methylcholanthrene.

6308 THE LIPOPROTEINS AND LIPID TRANSPORT IN ABETALIPOPROTEINEMIA. (E.) Levy, R. I. (NIH, Bethesda, Md.), D. S. Fredrickson and L. Laster. *J. Clin. Invest.* 45(4):531-541, 1966.
Extensive immunochemical investigation of serum lipoproteins was performed in 6 patients (age 7-37 yr.) with abetalipoproteinemia. Antisera were employed in either double diffusion or immunophoresis on agar and agarose to characterize the lipoproteins of D < 1.21. Antibody formation was provoked in rabbits by the admin. of lipoproteins obtained from 2 patients. The relative amino acid content and amino-terminal amino acid composition of the high and low density lipoprotein proteins were also determined. No trace of beta lipoprotein could be detected in any of the 6 patients by using multiple antisera in 3 different systems and against some samples that were more concentrated than plasma by 10-fold. Alpha-lipoproteins were the only lipoproteins present. Of these, 5-25% floated at D < 1.063 and more than 50% were isolated between D 1.063 and 1.1. The protein portions of these lipoproteins were immunochemically identical and had amino acid patterns indistinguishable from those in normal alpha proteins. Abnormal shifts in density were considered

GENERAL

likely due to excessive lipid loading of normal alpha-lipoproteins. The abnormally low plasma glycerides of these patients were unchanged, and no pre-beta (very low density) lipoproteins were produced by diets which regularly induce hyperglycemia in normal subjects and patients with alpha-lipoprotein deficiency. Results suggest that abetalipoproteinemia is due to an inability to synthesize or release the specific apoprotein of plasma beta-lipoproteins.

6309 TYPHOID CARRIERS - A FOLLOW-UP STUDY. (E.) Toussaint, J. (Ment. Hosp., Mont Park, Victoria, Australia). *Med. J. Aust.* 1(9):340-342, 1966.
In a study of 7 typhoid carriers (all females) in a mental hospital, treatment was started with ampicillin. If the carrier state persisted after 3 courses of ampicillin, other drugs were tried. These included streptomycin, sulfamethazine, Chloramphenicol, kanamycin, Terramycin, erythromycin, neomycin, and aureomycin. Follow-up was for 2.5 yr. With ampicillin only, one excretor ceased to be a carrier for 2 yr.; however, Vi agglutination was present throughout the period. Two others needed other drug treatment in addition to ampicillin to remain bacteriologically negative for 6 mo. Two excretors continued to excrete *Salmonella typhi* in spite of ampicillin and other drugs and cholecystectomy in one of the two. After mixed therapy one patient had no positive isolations while another became negative after one positive isolation.

6310 ENLARGEMENT OF SALIVARY GLANDS IN RATS AFTER CHRONIC ADMINISTRATION OF PHYSALAEMIN OR ISOPRENALINE. (E.) Bertaccini, G. (U. Parma, Italy), G. De Caro and R. Cheli. *J. Pharm. Pharmacol.* 18(5):312-316, 1966.
The effect of chronic admin. of physalaemin (10 or 100 µg/kg i.p. 4 times a day) or isoprenaline (400 mg/kg once or 50 mg/kg i.p. twice a day) on the salivary glands was studied in female Wistar rats. Enlargement of the salivary glands was marked (630% fresh wt. increase and 600% dry wt. increase as compared to control glands) after treatment with isoprenaline, but less pronounced with the higher dose. Physalaemin caused an increase in the wet and dry wt. which was moderate but significant (34% and 48%, resp.) with the low dose, but very slight and not significant (4%) with the larger dose. Histological examination revealed hypertrophy of the salivary glands of physalaemin-treated rats, while hypertrophy and hyperplasia with numerous mitoses and several nuclei in the spirema phase were observed in the glands of isoprenaline-treated rats.

6311 PATHOLOGY OF THE KIDNEY AND LIVER IN THE EXPERIMENTAL LEPTOSPIROSIS OF THE GUINEA-PIG. A LIGHT AND ELECTRON MICROSCOPY STUDY. (E.) De Brito, T. (Inst. Trop. Med., Sao Paulo, Brazil), E. Freymüller, S. Hoshino and D. O. Penna. *Virchow. Arch. Path. Anat.* 341(1):64-78, 1966.
A light and electron microscopic study of the kidney and liver was performed on guinea pigs usually 3-4 days or after 5-7 days after inoculation with *Leptospira icterohaemorrhagiae*. The earliest lesion found was located at the cell membrane, with partial or total disappearance of the brush border of the cells of the proximal tubules as well as partial disappearance and distortion of the microvilli of the hepatic cells. Intercellular spaces were found to be enlarged both in the liver and kidney. Capillaries showed endothelial cell tumefaction and, sometimes, disjunction of the endothelial lining, a finding also in accordance with the basic pathology of the disease. Organelles such as mitochondria were affected only late in the disease, often during the agonal period. However, a definite increase of "dense bodies," whose origin was discussed, was found starting with the early phase of the disease. Also described is a mild but definite focal glomerular lesion, which provides anatomical basis for the proteinuria seen in the disease. These observations indicate that a toxin is prominent in the pathogenicity of *Leptospira*.

GENERAL

- 6312 STUDIES ON THE USE OF THE INDIRECT HEMAGGLUTINATION TEST IN THE DIAGNOSIS OF AMEBIASIS. (E.) Milgram, E. A. (Commun. Dis. Ctr., Atlanta, Ga.), G. R. Healy and I. G. Kagan. Gastroenterology 50(5):645-649, 1966.
- When the indirect hemagglutination test (method of Kessel and Lewis) was employed on the sera of 121 patients with amebic liver abscess, 96% gave a positive response. Sera from 70 patients with no gastrointestinal symptoms at the time that Entamoeba histolytica was detected in stool specimens were essentially negative (91%). On the other hand the test was positive in 82% of 83 sera from patients who harbored E. histolytica and who had gastrointestinal symptoms at the time serum specimens were taken. Among 26 patients with gastrointestinal symptoms but without E. histolytica, 23 were negative. In this group were 8 with ulcerative colitis, 4 with strongyloidiasis, and 3 with shigellosis. In patients with infectious hepatitis there was 1 positive response among 22 patients; there were no positive responses among 2 with hepatoma and 7 with pyogenic liver abscess.

- 6668 CONTINUOUS FUNCTIONAL ARREST OF THE RECTAL SPHINCTER IN TREATMENT OF PARAPROCTITIS. (Rus.) Zhorov, I. S. and A. A. Blyakher. Vestn. Khir. Grekov. 96(1):64-69, 1966.

A review is presented of 485 cases of paraproctitis (341 acute, 144 chronic). The routine operative technic (early and wide exposure of a pararectal abscess) was used in 198 patients with acute paraproctitis; 90 patients were subjected to operation along with the use of blockade of the rectal sphincter with use of a local anesthetic (in oil) of long duration. Among a group of 114 chronic patients treated surgically, 97 were also subjected to blockade of the sphincter. In terms of late results, among 100 patients subjected to the routine operation, 46 developed fistulas and recurrence. Among the patients with surgery plus rectal sphincter blockade, good results were found in the patients with localized forms of acute paraproctitis. Unsatisfactory results were found mostly in patients with the diffuse forms of paraproctitis. The temporary immobilization of the sphincter in the surgical treatment of acute and chronic paraproctitis is recommended.

- 6669 THE PRUSSIAN-BLUE REACTION IN THE DIAGNOSIS OF PREVIOUS APPENDICITIS. (E.) Howie, J. G. R. (Western Infirm., Glasgow, Scotland). J. Path. Bact. 91(1):85-92, 1966.

In a study of 669 appendices, besides staining of sections with the usual hemalum and eosin, duplicate sections were examined by Perls' prussian-blue technic. The iron content of the appendices was assessed histologically and correlated with the clinical history and operative findings. Compared to a group where there was no history of earlier attacks of appendicitis, there were significant increases in the iron of appendices from patients with a positive past history of appendicitis and in those with "silent" appendicitis. Use of the prussian-blue technic, therefore, in the study of appendices appears to provide a useful index of previous appendicitis, and is of value as a diagnostic and research aid.

- 6670 IRRITABLE COLON SYNDROME IN EGYPTIANS WITH DESCRIPTION OF CASES CONDITIONED BY ANAL FISSURE. (E.) Elsheikh, A. (U. Cairo, Egypt). Gastroenterologia (Basel) 105(3):148-158, 1966.

Among 1,800 patients attending a private clinic for internal diseases, 702 (39%) had irritable colon syndrome. The sex ratio was about equal. The high incidence of irritable colon syndrome in Egypt (probably underestimated) was attributed to the prevalence of anxiety states and to a high incidence of dysentery (amebic and bacillary). There appeared to be a relationship between this syndrome and chronic anal fissure in 36 patients. This was indicated by the fact that block of the pudendal nerves by a long acting local anesthetic, or operative repair, led to relief of symptoms in most patients for a long period of time. A double-blind study indicated that the combined use of an anxiolytic drug (thioridazine, 25 or 10 mg) plus a tablet containing belladonna, ergotamine, and phenobarbital helped control the symptoms.

- 6671 POSTERIOR EXCISIONAL ANO-RECTAL MYOTOMY IN MANAGEMENT OF CHRONIC FAECAL ACCUMULATION. (E.) Bentley, J. F. R. Arch. Dis. Child. 41(216):144-147, 1966.

The technic of posterior excisional anorectal myotomy in the management of chronic fecal accumulation is described. The series of 22 young patients included an infant 6 wk. of age. Two patients had transient postoperative pyrexia. Some transient postoperative anal incontinence may last several wk. Among 7 with normal rectal biopsy histology, 2 boys and a girl have slowly lost their symptoms, but 1 girl remains unchanged. Ten had Hirschsprung's disease: 9 boys and 1 girl. In 9 yr. following operation, one 17-year-old boy has had no disability except for an acute episode of constipation that was precipitated by an attempt to curtail his

LARGE BOWEL

daily dose of paraffin emulsion. In all, 6 of the boys have been treated without major surgery, 3 have spontaneous daily bowel evacuation, but the other 3 continue to use suppositories or a laxative. Five (all boys) showed abnormal myenteric nerve with few ganglion cells. After operation all had a variable period of anal incontinence (up to several wk.) but all except 1 have slowly become clean and continent, though they need the occasional aid of small quantities of evacuants.

- 6672 INTRINSIC NON-PROPULSIVE COLON. (E.) Pagès, R. and B. Duhamel. Arch. Dis. Child. 41(216):151-152, 1966.

Thirteen young patients were observed in a Paris hospital with intestinal obstruction which was associated with intrinsic failure of colonic propulsion. The clinical picture was usually, but not always, associated with extensive lack of colonic ganglia. Histologic examination of the colon (surgical or necropsy specimens) showed some abnormality in the intrinsic nerve in 9 of the 13 patients. Six patients showed impairment of propulsion affecting the entire colon, with consequent gross distention of the small intestine. In 7 patients the defect in propulsion affected more than the left half of the colon. In the series as a whole, 8 patients died and only 5 survived following an extensive operation, despite the fact that proctocolectomy was avoided. There are grounds for including classic Hirschsprung's disease as a "short segment" variant of this syndrome.

Ulcerative Colitis

- 6742 EARLY COURSE OF ULCERATIVE COLITIS. (E.) Watts, J. McK. (Colitis Clin., Gen. Infirm., Leeds, England), F. T. de Dombal, G. Watkinson and J. C. Goligher. Gut 7(1):16-31, 1966.

In 204 adults and children with ulcerative colitis of recent onset (under 6 mo. in 90%), the av. follow-up period was 4.8 yr. The outcome of the first attack was: remission, 70%; improvement after treatment (unspecified), 16%; surgery, 11%; and death, 3.4%. The overall medical failure rate was 14.7%. The remission rate was highest in those patients with mild first attacks (88%) and only rectal involvement (85%), but only 2 patients had remissions lasting over 7 yr. The severity of the attack was related to the extent of intestinal involvement. The highest incidence of remissions (75%) and the mildest attacks occurred in patients aged 20-59 yr. at onset, but the extent of involvement decreased with age. The prognosis was worst in patients with rapidly developing symptoms. Of 56 patients requiring surgery, 9 died during the early postoperative period and 15 required 26 further operations (none died). The overall mortality rate was 4.0% in mild to moderate and 5.9% in severe first attacks; it increased to 12.2% in patients with substantial intestinal involvement. Mortality during the first attack increased in the older patients (below 20 yr. = 3.7%; 20-59 yr. = 2.3%; over 60 yr. = 21.1%); patients over 60 with severe attacks and extreme involvement had a mortality rate of 83%. The general health of the patients was good or excellent in 98% of the 185 survivors seen at the end of the 12-yr. study period.

- 6743 EARLY HISTOCHEMICAL CHANGES IN ULCERATIVE COLITIS. A LIGHT AND ELECTRON MICROSCOPIC STUDY. (E.) Donnellan, W. L. (Northwestern U. Sch. Med., Chicago, Ill.). Gastroenterology 50(4):519-540, 1966.

Twenty-seven patients (16 males, 11 females) with chronic idiopathic ulcerative colitis were studied by light and electron microscopy. Ages ranged from 15 mo. to 79 yr. Five were receiving corticosteroids at the time of the initial biopsy. Mucosal punch biopsies were taken when possible at 18 cm from the anal margin; in children the distance varied from 10-17 cm. Degeneration of the reticulin fibers of the colonic mucosa and dilation of the subepithelial capillaries are constant and early findings. Later in the course of the disease there is a progressive infiltration of the lamina propria with plasma cells and lymphocytes and, in some cases, with eosinophils and polymorphonuclear cells. Ulceration of the mucosa appears to be directly related to occlusion of the small vessels of the mucosa by platelet agglutination. A possible mechanism for the depletion of reticular collagen in ulcerative colitis is discussed. Steroids do not prevent the changes in collagen which were observed.

- 6744 CARBOHYDRATE INTOLERANCE IN ULCERATIVE COLITIS. (E.) Frazer, A. C. (U. Birmingham, England), C. Hood, R. D. Montgomery, A. G. Davies, R. Schneider, P. A. Carter and J. Goodhart. Lancet 1(7436):503-505, 1966.

Dietary carbohydrate restriction in 3 men with ulcerative colitis produced symptomatic improvement in all 3 cases. All had a history of diarrhea and a sigmoidoscopic confirmation of colitis; 2 were in their initial attacks and the third had colitis of 2 yr. duration. Reduction of total carbohydrate intake produced a decrease in stool vol., lactic acid, and fatty acids; the patients in the initial stages of disease had complete remission of the disease, and the other had a partial remission. Dietary carbohydrates were reintroduced slowly in the cases of complete remission without exacerbation of the symptoms, but the patient with only partial remission remained sensitive to a test dose of dietary lactose (100 g) when tested 3 mo. after the initial study. In this patient, a specific intestinal lactase deficit was later found. The authors suggested that the therapeutic effect of a milk-free diet in ulcerative colitis might be due to lactose intolerance rather than to protein sensitivity.

LARGE BOWEL

Ulcerative Colitis

- 6745 SURGICAL TREATMENT OF ULCERATIVE COLITIS IN CHILDHOOD. (E.) Ehrenpreis, T. (Karolinska Hosp., Stockholm, Sweden). Arch. Dis. Child. 41(216): 137-142, 1966.

There has been a marked increase in children with ulcerative colitis in Stockholm between 1919 and 1953, based on hospital admissions. The 45 children in the present series were 3-16 yr. old at the time of onset, and 9-19 yr. at operation. Operative treatment was as follows: pan-coloproctectomy plus ileostomy (17); colectomy plus ileostomy (9); and colectomy plus anastomosis (19). There were 2 postoperative deaths. There were 49 complications among 27 patients: 18 made an uneventful recovery; 3 children required tracheostomy and respiratory treatment. Fourteen patients had 21 episodes of small bowel obstruction; another common complication was wound rupture or infection (13). In a period of follow-up of 8 mo. to 12 yr. after operation, there have been no late deaths. The majority gained 10-20 kg in wt. during the first 6 mo. Signs of physical and emotional retardation ceased, and development subsequently became adjusted to normal proportions.

- 6746 ARTICULAR COMPLICATIONS OF ULCERATIVE COLITIS. (E.) Wright, V. (U. Leeds Sch. Med., England) and G. Watkinson. Am. J. Proctol. 17(2): 107-115, 1966.

All 269 patients with ulcerative colitis who presented themselves on one particular day were examined by a gastroenterologist and a rheumatologist. Rheumatic complaints were found in 45% of the group. Fifteen patients had ankylosing spondylitis; 31 (11.5%) developed a specific type of arthritis designated colitis arthritis. This disease was distinct from rheumatoid disease clinically, serologically and radiographically. In a radiographic study of the sacro-iliac joints and lumbar spine of 234 patients, 18% of the patients had sacro-ileitis. This represents a highly significant increase in incidence compared with the control population. The sacro-ileitis showed an equal sex incidence while the ankylosing spondylitis affected men more commonly than women.

EXOCRINE PANCREAS

- 6755 THE EFFECT OF IRRADIATION ON THE FINE STRUCTURE AND ENZYMES OF THE DOG PANCREAS. I. SHORT-TERM STUDIES. (E.) Volk, B. W. (Issac Albert Res. Inst., Brooklyn, N. Y.), K. F. Wellmann and A. Lewitan. Am. J. Path. 48(5):721-753, 1966.

After a single large dose (5,000-9,000 r) of roentgen rays to the exteriorized pancreatic remnant in 23 dogs (after pancreatectomy), studies of enzymes and ultra-structure were made at intervals from 30 min. to 21 days. Acinar cells exhibited large numbers of membrane-bound cytoplasmic lesions, with varied patterns. These contained altered cytoplasmic components as well as a variety of pleomorphic electron-dense structures consisting of osmiophilic agranular membranes, vacuoles and granules of varying size and shape. Max. acinar cell damage was manifest 5 to 8 days after treatment. Between the twelfth and 21st days the number of lesions was reduced, although various pleomorphic alterations were still evident. There was also a reduction in the number and size of mature zymogen granules which became more prominent with time. Simultaneously the amount of pancreatic amylase, lipase and leucine aminopeptidase appeared lessened. Islets exhibited moderate degranulation, swelling of mitochondria, distention of endoplasmic reticulum and the appearance of dense bodies in a number of B cells. Several A cells displayed cystic dilatation of the endoplasmic reticulum, deposition of a finely granular intracytoplasmic material and swelling of mitochondria. In contrast to the acinar cells the alterations in islet cells became more conspicuous near the end of the experimental period. Despite the B cell changes daily blood sugar levels and glucose tolerance tests maintained normal values.

- 6756 HYPOGLYCEMIA DUE TO OBSTRUCTION OF PANCREATIC EXCRETORY DUCTS BY CARCINOMA. (E.) McBee, J. W. (2002 Holcombe Blvd., Houston, Texas), F. L. Lanza and E. E. Erickson. Arch. Path. (Chicago) 81(4):287-291, 1966.

Case histories are presented for 2 men (a 43-year-old Caucasian and 45-year-old Negro) who died in a state of severe hypoglycemia. Diabetes had been diagnosed in the latter but could not be established in the former. At autopsy, both had a well-differentiated columnar cell adenocarcinoma of the head of the pancreas. In these cases there was apparent obstruction of the pancreatic excretory ducts with subsequent atrophy of the acinar tissue distal to the lesion and hyperplasia and neoformation of islet tissue. A probable mechanism for these changes is reviewed.

- 6757 THE PATTERN OF PAROTID GLAND SECRETION IN CYSTIC FIBROSIS OF THE PANCREAS. (E.) Marmar, J. (Child. Hosp., Philadelphia, Pa.), G. J. Barbero and M. S. Sibinga. Gastroenterology 50(4):551-556, 1966.

Subjects studied were 12 children with cystic fibrosis of the pancreas and 13 healthy school children. Parotid saliva was collected by placing a Lashley cup over the papilla of Stenson's duct. Reflex salivation was stimulated by sucking an orange-flavored lozenge. Parasympathomimetic stimulation was obtained by s.c. inj. of methacholine chloride (2.25 mg). Flow rates and sodium, potassium, chloride, and calcium conc. were determined for separate collection periods. Secretory rates in patients with cystic fibrosis were elevated under all circumstances. With reflex stimulation and in the pooled sample after methacholine stimulation sodium was significantly elevated in cystic fibrosis patients. Calcium conc. were not elevated after reflex stimulation but were after methacholine stimulation. Calcium excretion was found to become relatively more elevated as secretion proceeded.

- 6758 PREGNANCY IN CYSTIC FIBROSIS OF THE PANCREAS. (E.) Grand, R. J. (NIH, Bethesda, Md.), R. C. Talamo, P. A. di Sant'Agnese and R.H. Schwartz. J.A.M.A. 195(12):993-1000, 1966.

EXOCRINE PANCREAS

Two case histories are presented of cystic fibrosis patients who became pregnant. Disease was diagnosed at ages 18 and 23 yr. A white woman bore 2 normal children. The second patient, a Negro, suffered progressive pulmonary decompensation during and following pregnancy. The patient precipitously delivered a macerated, still-born male infant. The respiratory decompensation did not respond adequately to therapy and patient died on day 11 of her hospital admission. By questionnaire, a total of 8 other patients with cystic fibrosis were found who had been pregnant. Of the entire 10, a total of 5 showed pulmonary decompensation associated with pregnancy; 2 of these died in the postpartum period. There were 2 cases of overt diabetes mellitus which were well-documented prior to pregnancy. There were 4 premature living, and 1 stillborn fetuses. The 11 living infants of the 13 pregnancies are currently free of the clinical manifestations of cystic fibrosis.

- 6759 INFLUENCE OF A FAT DIET ON THE MORPHOLOGY AND FUNCTION OF THE EXOCRINE PANCREAS. (EXPERIMENTAL STUDIES.) (It.) Fontana, G. (U. Bologna, Italy). Riv. Pat. Clin. 20(10):505-529, 1965.
Morphological and functional studies of the exocrine pancreas were performed in male Sprague-Dawley rats fed balanced, high-fat, or high-fat and high-protein diets. At electron microscopy, rats fed high-fat diets showed changes in pancreatic acinar cells which consisted of a decrease in zymogen granules, mitochondrial swelling, and dilatation of the endoplasmic reticulum with reduction in the number of ribosomes; lipid accumulation was observed in endothelial and acinar cells and in the capillary lumen; marked decrease in pancreatic amylase, lipase, and trypsin levels was also observed. Changes were more marked after 10 days of feeding than after 6 days. Upon return to a balanced diet after 10 days of high-fat diet, most of the morphological alterations were absent but pancreatic enzyme levels were still decreased. In rats fed a high-fat and high-protein diet, acinar cells failed to show changes in mitochondria and endoplasmic reticulum, although fat accumulation was still significant; initial decrease in pancreatic amylase, and subsequent decrease in lipase activity, were observed. Upon return to balanced diet after 10 days of high-fat and high-protein diet, the acinar cells of the pancreas were normal, indicating that the morphological changes induced by this type of diet are reversible.

- 6765 ARTERIAL HEMORRHAGE IN PSEUDOCYST OF PANCREAS. (E.) Bucknam, C. A. (511 S. Floyd St., Louisville, Ky.). Arch. Surg. (Chicago) 92(3):405-406, 1966.

Pancreatitis

- 6766 ACUTE PANCREATITIS. (E.) McCollum, J. K. (Newcastle Gen. Hosp., Newcastle-Upon-Tyne, England). J. Indian Med. Prof. 12(12):5664-5666, 1966. During a 10-yr. period after 1954, acute pancreatitis was diagnosed in 31 patients: 27 females and 4 males. The av. age at onset of the acute illness was 64 yr. Seven were subjected to laparotomy after recovery from the acute pancreatitis; gallbladder stones were removed in all instances. Three patients have died; 1 died 15 days after laparotomy. A second died 7 yr. after the acute attack. The third died in acute circulatory failure within 24 hr. of the onset of acute pancreatitis. Patients have been followed from 1-9 yr. (av. 5 yr. and 2 mo.). In 14 patients who had no evidence of biliary tract disease before the acute episode, 13 have survived and none have had any subsequent significant abdominal disability. There have been 12 survivors in a group of 14 with abnormality in the biliary tract. Seven have had operations which included choledochotomy and dilatation of the sphincter of Oddi and 6 of these 7 have had no further disability. In one, recurrent pain and jaundice have necessitated re-exploration of the common bile duct, removal of biliary gravel, and repeat dilatation of the lower end of the duct. Two of 5 patients in this group have required readmission because of further episodes of acute pancreatitis.
- 6767 TREATMENT OF CHRONIC PANCREATITIS. (Fr.) White, T. T. (U. Washington Sch. Med., Seattle). Lyon Chir. 61(6):801-814, 1965. Roux-Y side-to-side pancreaticojejunostomy was performed in 15 patients with chronic pancreatitis (13 of alcoholic origin); pain relief lasting 1-6 yr. was observed in 12 of 15 patients; of the 3 failures, 2 were among alcoholic patients and 1 was in a non-alcoholic patient. Although steatorrhea was not improved by this method, diabetes was improved postoperatively in 2 patients. Among patients with chronic pancreatitis of alcoholic origin treated by other methods, failure occurred in 5 of 5 patients treated by cystoduodenal (3) or cystogastric (2) anastomosis, in 3 of 3 patients treated by splanchnicectomy or splanchnic block (effective only in non-alcoholic patients where biliary pathology had been treated), and in 6 of 6 patients treated by sphincterotomy and pancreatic duct drainage. Pancreatic resection using the modified Mallet-Guy technic is indicated in cases of failure of anastomosis or splanchnicectomy.
- 6768 THERAPEUTIC TRIALS WITH EPSILON-AMINOCAPROIC ACID IN EXPERIMENTAL ACUTE PANCREATITIS. (Sp.) Linares, C. A. (Ramos Mejia Hosp., Buenos Aires, Argentina) and C. J. L. Morel. Rev. Argent. Cir. 9(1):13-15, 1965. Acute pancreatitis was induced by a method described in the following abstract in 30 dogs (wt. 10-30 kg); 15 of the dogs also received i.v. inj. of ϵ -aminocaproic acid (500 mg/kg/day in 3 divided doses) for 4 days. Histological examination revealed no significant therapeutic effect in treated dogs as compared to controls. Among treated animals, however, 2 survived and 4 died later (96-168 hr.) than those in the control group. Serum amylase levels (Somogyi method) were higher (166%) in treated animals than in controls (37%). Although some protective action may be due to the antifibrinolytic effect of ϵ -aminocaproic acid, the authors feel that it is not enough to prevent death.
- 6769 EXPERIMENTAL INDUCTION OF ACUTE PANCREATITIS IN THE DOG BY CONNECTION OF THE COMMON BILE DUCT TO THE PRINCIPAL PANCREATIC DUCT. (Sp.) Linares, C. (Ramos Mejia Hosp., Buenos Aires, Brazil), G. Faraj Cualli and C. J. L. Morel. Rev. Argent. Cir. 9(1):16-18, 1965. A technic is described for the establishment of a biliopancreatic communication by means of a polyethylene catheter. Ten mongrel dogs treated this way died of acute pancreatitis in 56-120 hr. Serum amylase levels (Somogyi method) were 80% higher in operated animals than in controls. Histological studies of the pancreas revealed a typical picture of acute pancreatitis with predominance of necrosis and hemorrhage.

EXOCRINE PANCREAS

Pancreatitis

In some animals bile pigment was found in the pancreatic duct. No significant changes were observed in the gallbladder or bile ducts, while the liver showed moderate congestion of the portal and centrilobular spaces. (See also the preceding and following abstracts.)

- 6770 EFFECTS OF ANASTOMOSIS OF THE GALLBLADDER WITH THE PRINCIPAL PANCREATIC DUCT IN DOGS. (Sp.) Faraj Cualli, G. (Ramos Mejia Hosp., Buenos Aires, Argentina), C. Linares and C. J. L. Morel. Rev. Argent. Cir. 9(1):23-26, 1965.

Of 10 dogs in which the gallbladder was connected to the pancreatic duct by means of a polyethylene catheter, all survived and 5 were sacrificed 35-60 days after surgery; no alterations of the liver, pancreas, or biliary tract were observed. Ten other dogs were subjected to the same surgical procedure as above in addition to section and ligation of the common bile duct; all animals died 3-6 days after surgery; histological examination of the pancreas revealed intense necrotico-hemorrhagic pancreatitis. Five other dogs treated by gallbladder-pancreatic duct anastomosis in association with delayed common bile duct obstruction (induced by constriction through a polyethylene catheter) died 4-6 days after surgery; histological examination of the pancreas revealed a picture of acute pancreatitis with necrosis and hemorrhage similar to that of the previous group. Results indicate that mere passage of pancreatic juice through the biliary tract does not cause inflammatory or degenerative changes, whereas the presence of bile in the pancreas causes necrotic and hemorrhagic lesions of this organ. (See also the preceding two abstracts.)

- 6771 SERUM TRYPSIN ACTIVITY (ARGININE METHYL ESTERASE). ITS USE IN THE DIAGNOSIS OF CHRONIC PANCREATITIS. (It.) Fontana, G. (U. Bologna, Italy), P. Puddu, F. Faggioli and P. Azzaroli. Gior. Clin. Med. 46(12):1177-1204, 1965.

Serum trypsin activity (based on liberation of methanol by the hydrolysis of p-tosyl-L-arginine methylester hydrochloride (L-TAME) according to the method described by Siegelman *et al.*; normal values 10-50 μ moles of L-TAME/ml/hr.) was determined in 26 patients (age 34-71 yr.) with chronic pancreatitis, most confirmed at biopsy. Basal serum trypsin values were higher than normal in 9 patients; values after stimulation with pancreozymin and secretin were higher than normal in 12 patients. Elevated serum trypsin activity was frequent in recurrent pancreatitis (shortly after acute phase) and in chronic pancreatitis associated with impaired pancreatic secretion. The authors feel that the determination of serum trypsin activity can be a valuable aid in the diagnosis of chronic pancreatitis.

- 6772 ANALYSIS OF RESULTS OF 146 LEFT SPLANCHNICECTOMIES WITH CELIAC GANGLIECTOMY FOR CHRONIC AND RECURRENT PANCREATITIS. (STATISTICS OF P. MALLET-GUY, 1942-1959). (Fr.) White, T.-T. (U. Lyon Fac. Med., France), M. Lawinski, G. Stacher, J. Pangtay Tea and J. Michoulier. Presse Med. 74(13):645-647, 1966.

Among 146 patients subjected to left splanchnicectomy with celiac gangliectomy from 1959-65, a follow-up of 5 yr. was possible in 116. Of 39 patients with predominantly fibrous or calcifying pancreatitis, surgical results were excellent in 11 and good in 8, while 8 others showed some improvement; overall positive results were 69.2%; of 12 failures (30.8%), 3 died from progression of pancreatic disease. Of 44 patients with diffuse parenchymatous pancreatitis in association with biliary lithiasis (choledocholithiasis and cholecystitis excluded), surgical results were excellent in 34 and good in 4, while 3 showed some improvement; overall results were positive in 93.2% and negative in 6.8%. Of 33 patients not included in either of the 2 groups mentioned above, surgical results were excellent in 19 and good in 4, while 6 others showed some improvement; overall results were positive in 87.9% and negative in 12.1% (1 patient died from progression of disease). Among the 116 patients, associated operations included Kehr drainage (9), cholecystectomy (52), gastric surgery (4),

biliary derivation (20), and splenectomy (1). Total results (116 patients) were positive in 83.6% and negative in 16.4% (15 failures; 4 deaths).

- 6773 PANCREATITIS INDUCED BY THE GRAFT-VERSUS-HOST REACTION. (E.) Walters, M. N-I. (U. Western Australia, Perth). J. Path. Bact. 91(1):65-69, 1966. A suspension of spleen cells from Prince Henry Hospital mice was adjusted to a conc. of 20×10^6 cells/ml. When infant Royal Perth Hospital mice received 0.05 ml of this suspension i.p., by the end of the third wk. they were usually moribund and were sacrificed. Severe granulomatous pancreatitis occurs in the runting syndrome so induced. After glandular necrosis, sheets of lymphocytes and macrophages, arising from the lymphoreticular aggregates of the covering serosa, disseminate as an inflammatory pannus throughout the pancreatic interstitium. Only the degenerating remnants of acini, islets and ductules remain. This type of reaction is considered to have but little etiologic significance as far as human pancreatic disease is concerned.

LIVER AND BILIARY TRACT
GENERAL

- 6785 STUDIES OF SO-CALLED INFILTRATIVE HEPATITIS IN CHILDHOOD. (Ger.) Mahnke, P.-F. (U. Leipzig, Germany) and B. Gantenbein. Zbl. Allg. Path. 108(4): 412-416, 1966.

Five cases of typical infiltrative hepatitis were seen among 200 autopsy liver specimens from children. Characteristic findings included conc. of WBC and lymphocytes such as those frequently seen in connection with inflammatory processes, massed in such a way as to obstruct the hepatic veins, especially the central veins and those which drain the area. All of the children were infants (aged 10 days-4 mo.) and all had died of pneumonia. The primary disorders were pneumonia, myelomeningocele, myelomeningocele with spinal leptomeningitis, peritonitis following intestinal infarct (in a child with umbilical hernia), and mongolism with rectal and anal atresia. The infiltrative hepatitis described was a non-specific, although unusually clearly localized, hepatic reaction to extrahepatic disease.

- 6786 SIGNIFICANCE OF STEROID HORMONES FOR THE DEVELOPMENT OF HYPERBILIRUBINEMIA AND NEONATAL JAUNDICE. (Ger.) Lauritzen, C. (U. Kiel, Germany) and W. D. Lehmann. Zschr. Kinderheilk. 95(2):143-154, 1966.

In 8 normal newborn infants, admin. of estriol, pregnanediol, or cortisone during the first 2 wk. of life caused an increase in serum unconjugated bilirubin, but progesterone had no effect. Estriol, progesterone, cortisone, and pregnanediol, when admin. to nursing mothers, were excreted via the milk and resulted in an increase in serum bilirubin in the infants. Therapeutic doses of prednisolone, dexamethasone, triiodothyronine, dehydroepiandrosterone, and the anabolic steroids 19-nortestosterone phenylpropionate (Durabolin) and 17 α -methandrostenolone acetate (Primobolan) were also without effect; triiodothyronine did not affect the increase in serum bilirubin seen in infants treated simultaneously with estriol. The phenomenon is explained as an effect of competition between these steroids and bilirubin for glucuronosyl transferase in the liver of newborn infants. The high quantities of placental and fetal hormones that must be conjugated and excreted in the first few days of life compete with bilirubin for the conjugating enzyme. This hypothesis was confirmed by another study in newborn infants, showing that serum bilirubin levels were not elevated after admin. of the glucuronide conjugates of estriol, pregnanediol, or deoxycorticosterone.

- 6787 HEPATIC BLOOD FLOW IN HEPATOSPLENIC BILHARZIASIS. (E.) Mousa, A. H. (Cairo U., Egypt), A. A. Atta, A. El Rooby, A. A. El-Garem, M. Saif and A. Zein El-Abdin. J. Trop. Med. Hyg. 69(2):45-50, 1966.

In 60 patients with early or late schistosomiasis, hepatic blood flow (estimated by Au¹⁹⁸ or sulfobromophthalein clearance) was within the normal range in all patients except those who showed extensive collateral circulation. There was a marked negative correlation between hepatic blood flow and intrasplenic pressure in patients with collaterals, but there was no correlation between hepatic blood flow and spleen size in patients with or without collaterals. Maintenance of liver circulation within normal limits may have resulted from an increase in portal pressure (up to a certain limit) and total blood vol. Arterial compensation via the hepatic artery was noted in patients with schistosomiasis, but not in those with true cirrhosis.

- 6788 COLORIMETRIC DETERMINATION OF SERUM GUANASE ACTIVITY. (E.) Caraway, W. T. (McLaren Gen. Hosp., Flint, Mich.). Clin. Chem. 12(4):187-193, 1966.

The method is based on the determination of ammonia (liberated by the deamination of guanine by guanase) by the Berthelot phenate-hypochlorite reaction. The rate of guanine deamination was independent of conc. and linear with time up to 2 hr. Guanase activity was also independent of pH over the range 6.5-8.1. The rate of the guanase reaction was directly proportional to the serum guanase conc.; nominal activity under standard conditions was 38.8 U/1000 ml. Guanase activity rose

LIVER AND BILIARY TRACT

2.4-fold when the incubation temperature was increased from 25° to 37°C; about 10% of the guanase activity was lost when the serum was preincubated for 30 min. at 56° before assay at 37°. The results were reasonably reliable using whole serum, but more reliable with protein-free supernatants. In 39 patients without hepatobiliary disease (including patients with duodenal ulcers and pancreatitis), serum guanase activity was 0-3 U/1000 ml. Serum guanase activity increased parallel to serum glutamic-oxaloacetic transaminase activity in patients with jaundice resulting from acute hepatocellular disease, but was normal in other jaundiced patients with extrahepatic obstruction without secondary hepatocellular involvement. The significance of guanase determination in the differential diagnosis of jaundice is discussed.

- 6789 **ROLE OF AZYGOS VENOUS SYSTEM IN THE INVESTIGATION OF PORTAL HYPERTENSION.** (E.) Murray, M. J. (U. Minnesota Sch. Med., Minneapolis). Gut 7(1):94-98, 1966.

Studies were conducted in dogs 1-2 mo. after the second of 2 operations in which portal systemic collaterals were prepared and portal hypertension was induced by obstruction of the portal vein to decide if azygos vein catheterization was a useful approach to the study of portal hypertension with collateral flow. Azygos catheterization was found to be both a practical procedure and a reliable indicator of portal pressure. Increased oxygen content of the azygos blood appeared to be a sign of collateral flow. No increase in catecholamine or serotonin in azygos blood could be found but the ammonia content was higher in the animals with collateral flow than in control animals. Using indicator substances instilled into the jejunum the collateral circulation could be readily detected and quantitated crudely by sampling from the azygos and hepatic veins. It would appear that these methods are entirely applicable to humans and preliminary studies in patients with cirrhosis support this hypothesis.

- 6790 **ACCIDENTAL LIGATION OF THE HEPATIC ARTERY.** (E.) Monafu, W. W., Jr. (4960 Audubon Ave., St. Louis, Mo.), J. L. Ternberg and R. Kempson. Arch. Surg. (Chicago) 92(4):643-652, 1966.

Case reports of 11 adults without significant preexisting hepatic parenchymal disease who had accidental ligation of one of the major divisions of the hepatic artery are presented. The accidents occurred during cholecystectomy or pancreaticoduodenal resection (4 cases each) and once during gastrectomy, nephrectomy, and repair of a hepatic artery aneurysm. Hepatic necrosis was proved by biopsy or autopsy in each of the 8 patients who died and was judged to be the cause of death. Three of the 4 patients who underwent reconstruction of their hepatic artery survived. Detailed postoperative study of hepatic function was performed in four cases. Extreme, sustained elevations of serum glutamic oxalacetic and serum glutamic pyruvic transaminases were observed in those who died of hepatic necrosis. Arterial reconstruction of nonfatal hepatic infarction was associated with a smaller rise in the serum levels of these enzymes followed by a return of them to normal after 5-10 days. Mild bilirubinemia and a delayed rise and fall in the serum alkaline phosphatase were also observed in those who survived.

- 6791 **THE LEVEL OF HIGHLY-UNSATURATED FATTY ACIDS IN THE BLOOD SERUM IN CHRONIC HEPATITIS AND LIVER CIRRHOSIS.** (Rus.) Velikov, V. K. Ter. Arkh. 38(1):47-50, 1966.

The serum of patients with chronic epithelial hepatitis tended to have a decreased amount of linoleic and arachidonic acids, which, however, was not significant. Linolenic and pentanoic acids remained normal. In patients with liver cirrhosis (55 as a result of chronic epithelial hepatitis) there was a statistically significant decrease of linoleic acid and a less pronounced decrease of the other polyenes. In patients with chronic mesenchymal hepatitis, all of the acids were increased in the serum; this increase was correlated with a high content of cholesterol in most of the patients. Similar results were found also in 4 patients with mechanical jaundice and in 1 patient with xanthomatosis. In one of two patients with subacute

LIVER AND BILIARY TRACT

dystrophy the levels of polyenic acids were markedly increased after recovery; content 6 mo. later was somewhat below normal. It is therefore suggested that the diet of chronic hepatitis patients be supplemented with additional amounts of vegetable oils.

- 6792 PROTEIN CHARACTERISTICS OF SERUM AND BILE ALKALINE PHOSPHATASE. (E.)
Pope, C. E. II (Boston City Hosp., Mass.) and S. R. Cooperband.
Gastroenterology 50(5):631-636, 1966.

Gallbladder bile was obtained from the gallbladders of 15 patients undergoing laparotomy for diseases unrelated to the hepatobiliary tree and from the gallbladders of 31 patients with cholelithiasis or inflammatory disease of the hepatobiliary system. The isozyme pattern was determined by horizontal starch gel electrophoresis. The isozymes of alkaline phosphatase found in the bile do not resemble those found in the serum. Incubation of bile with serum does not convert the serum alkaline phosphatase isozymes to a pattern resembling those found in bile. Ultracentrifugation of serum and bile shows that serum and bile alkaline phosphatase have approx. similar molecular sizes. These findings suggest that bile alkaline phosphatase does not represent an excretion product of serum alkaline phosphatase.

- 6793 THIN LAYER CHROMATOGRAPHY OF SERUM CHOLESTEROL ESTERS IN PATIENTS WITH VARIOUS HEPATIC DISEASES. (It.) Tucci, G. (U. Bologna, Italy), L. Gandolfi, L. Frizziero and O. Masiello. Rass. Fisiopat. Clin. Ter. 37(2):114-128, 1965.

Serum cholesterol esters were determined by thin layer chromatography (Zöllner method) in 18 normal subjects and in 33 patients with various liver diseases, including cirrhosis (18), obstructive jaundice (7), acute hepatitis (6), sclerosis (1), and hepatic metastasis from breast cancer (1). Among normal subjects, serum levels were highest for esters of di- (39.4%) and mono-unsaturated (26%) fatty acids. Among patients with hepatic disease, mono-unsaturated fatty acid esters were increased in all groups, with highest levels in patients with biliary cirrhosis (39.4%) and slightly above normal levels in patients with obstructive jaundice (34.3%). Di-unsaturated fatty acid esters were significantly decreased in patients with acute hepatitis (33%), hepatic cirrhosis (35.7%), and biliary cirrhosis (32.8%). Cirrhosis patients also showed a decrease in esters of tri- and tetra-unsaturated fatty acids. Contrary to other hepatic diseases, obstructive jaundice was usually accompanied by a decrease in saturated fatty acid esters (13.3% as compared to normal values of 17.6%). Results seem to indicate that the insufficient liver is able to utilize better the esters of polyunsaturated fatty acids, and that impaired absorption of fats in various hepatic diseases is not a contributing factor.

- 6794 EFFECT OF LIVER DISEASE UPON STEROID CIRCADIAN RHYTHMS IN MAN. (E.)
Tucci, J. R. (Georgetown U. Sch. Med., Washington, D. C.), R. A. Albacete and M. M. Martin. Gastroenterology 50(5):637-644, 1966.

Plasma and urinary unconjugated, plasma conjugated and urinary total 17-hydroxycorticosteroid levels were determined in 6 consecutive 4-hr. periods; the plasma levels were measured at the midpoint of each urine collection. In 11 patients with known liver disease (cirrhosis), plasma unconjugated as well as conjugated 17-hydroxycorticosteroid levels were within the normal range in the morning. Plasma unconjugated 17-hydroxycorticosteroids demonstrated a circadian variation within the broad limits of normal in 4 of 8 patients with liver disease studied. In the remaining 4, peak levels were maintained longer than normal or else the variation was markedly reduced. Plasma conjugated 17-hydroxycorticosteroids showed a slower than normal rise and broader peak resulting in inversion of the normal diurnal rhythm in 6 of the 8 patients investigated. The urinary findings reflected the plasma changes. The 24-hr. excretion of free 17-hydroxycorticosteroids in the urine was significantly greater than in the normal subjects, whereas total 17-hydroxycorticosteroids excretion was reduced.

LIVER AND BILIARY TRACT

- 6795 LIVER PATHOLOGY IN MALNOURISHED NEW GUINEANS. (E.) Bailey, K. V. (Nutr. Res. Unit, Kundiawa, Territory of Papua & New Guinea). Med. J. Aust. 1(14):572-575, 1966.

The Chimbu highlanders who form the basis of this report chiefly eat the sweet potato, which supplies over 80% of the calories and 50% of the protein of the diet. In 1961, hospital admissions included the following: kwashiorkor, 43; marasmus 171 (7 mo.-5 yr. 105; 1-6 mo. 66); malnutrition 14 (6-15 yr.). Biopsy and autopsy material revealed mild fatty change which was found in most of the children with kwashiorkor and in about half of the children with marasmus. Fatty change was not seen in the livers of 5 healthy lactating women but occurred in 8 of 17 with nutritional edema. Large, swollen cells with clear, pale-staining cytoplasm and a thickened cell membrane were frequently seen in the specimens, forming sheets with a distinctive mosaic of wire-netting appearance. Portal fibrosis was not seen in children with kwashiorkor but was seen in some children suffering from malnutrition.

- 6796 SPLENOPORTOGRAPHY IN BUDD-CHIARI'S SYNDROME AND DISEASE. (E.) Chudáček, Z. (U. Pilsen Hosp., Czech.). Radiol. Clin. (Basel) 34(4):247-253, 1965.

Two cases of Budd-Chiari's syndrome are presented. A 20-year-old woman developed sepsis after abortion, accompanied by hepatomegaly. Roentgenograms showed mild splenomegaly but pronounced hepatomegaly. Splenoportography visualized the vena coronaria ventriculi as well as the venous system of the esophagus. Contrast medium persisted in the splenic vein and its tributaries after it had disappeared from the liver. Ascites developed several days later, the surface of the liver became uneven, and the patient died 14 days after splenoportography. Postmortem examination revealed that the inferior vena cava under the diaphragm was filled with old, de-colored thrombus, under which was found recent stagnation thrombosis. The second case concerned a 16-year-old boy with edema of the lower extremities, ascites, caput medusae, and arterial hypertension. Splenoportography revealed a slightly enlarged spleen, considerably enlarged liver, portal hypertension and normal ramification of the portal vein in the liver. Contrast medium persisted for a long period in the splenic vein, its tributaries and liver. There was incomplete obstruction of the inferior vena cava at the level of T 9 up to L 1. The renal vein on the right side was displaced in a distal direction. A pneumoretroperitoneum verified a tumor of the right adrenal gland.

- 6797 THE ULTRASTRUCTURE OF ACIDOPHILIC "COUNCILMAN-LIKE" BODIES IN THE LIVER. (E.) Klion, F. M. (Mt. Sinai Hosp., New York, N. Y.) and F. Schaffner. Am. J. Path. 48(5):755-767, 1966.

An ultrastructural study is presented of the liver of 5 adults with hepatitis, 2 children with hepatoma, and of auxiliary liver which was transplanted into the pelvis of 3 dogs 6-8 days previously. The acidophilic bodies found apparently represent a form of hepatocellular injury which can occur in species other than man and which does not indicate any specific etiologic agent. The ultrastructure of acidophilic bodies clearly reaffirms their hepatocellular origin since they contain rosettes of particulate glycogen and organelles similar to those in normal hepatocytes. These "Councilman-like" acidophilic bodies constitute entire cells containing condensed hyaloplasm. These are separated from their neighbors and are surrounded by macrophages and may represent a later stage of the so-called "dark cells."

- 6798 CLINICAL EVALUATION OF LIVER SIZE AND HEPATIC SCINTISCAN. (E.) Peternel, W. W. (U. Cincinnati Coll. Med., Ohio), J. W. Schaeffer and L. Schiff. Am. J. Dig. Dis. 11(5):346-350, 1966.

The clinical estimation of liver size was evaluated in 21 adults without known liver disease and 22 with various diseases of the liver. Radioisotope scintiscans were used as a standard of comparison. For liver scintiscans, most patients were given (after thyroid blockade) 150 μ c of ^{131} I-rose bengal i.v.; several subjects received a dose of 150 μ c of Au^{198} . It was found that the upper border of liver dullness

LIVER AND BILIARY TRACT

(as delineated by percussion) was almost always too low. The normal liver may frequently extend below the costal margin and the xiphoid process and yet be impalpable.. Percussion offers a more accurate means of estimating the lower border of the normal or the acutely diseased liver. A truer estimation of liver size is obtained in patients with chronic liver disease, presumably because the increased consistency of the organ enhances the detection of its lower border by physical examination.

- 6799 AN EXPERIMENTAL STUDY ON HEMORRHAGIC SHOCK; PARTICULARLY ON PECULIARITY OF SHOCK CAUSED BY HEMORRHAGE FROM THE PORTAL VEIN. (Jap.) Saiki, H. (Kanazawa U. Sch. Med., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 35(2):331-345, 1966.

Groups of dogs were bled from either the portal or femoral vein by two procedures: intermittent withdrawal (5 ml/kg every 30 min.) or continuous withdrawal. Changes related to the general circulation such as arterial and venous pressure, and circulating plasma vol. were similar in all 4 groups of dogs. In contrast to these findings, portal pressure showed a characteristic increase as shock levels were reached by either method of blood withdrawal. Infusion of fluids or the return of blood in this situation resulted in elevation of the pressure. Shortening of survival time, disturbance of liver function and parenchymal impairment of the liver were all more intense in the group in which blood was withdrawn from the portal vein than in the group in which blood was withdrawn from the femoral veins.

- 6800 ARTERIALIZATION OF THE LIVER IN PLACEMENT OF PORTACAVAL ANASTOMOSIS. (Rus.) Khanin, M. N. (Tashkent Inst. Med., USSR), T. G. Mankus, B. S. Sadreddinov, B. I. Kinel, S. M. Prigozhina and E. N. Ostoumova. Pat. Fiziol. Eksp. Ter. 9(6):35-38, 1965.

In a control series of 5 dogs with portacaval anastomosis only, vomiting, loss of wt., and exhaustion were noted. Encephalopathy was observed in 4 of the dogs during the first 10 days; this condition recurred after treatment with glucose or milk plus sugar. These 4 dogs were sacrificed after 4-8 wk. in a condition of extreme exhaustion. Only 1 dog of the 5 was in satisfactory condition 3 mo. after surgery. None of 6 dogs subjected to portacaval anastomosis but with anastomosis of the splenic artery with the proximal end of the portal vein showed encephalopathy or vomiting after feeding; 3 days after feeding with meat nearly all the dogs ate poorly. Three showed loss of wt., 2 gained wt. and 1 showed no change. One dog died 4.5 mo. after surgery but the cause of death could not be determined.

- 6801 EFFECT OF LIVER AND BILIARY TRACT DISEASES ON THE DEVELOPMENT OF ATHEROSCLEROSIS. (Rus.) Lukash, N. V. (Crimean Inst. Med., Simferopol, USSR) and R. A. Kaganovich. Ark. Pat. 27(12):63-65, 1965.

Fifteen days after insertion into the gallbladder of rabbits of 3 cholesterol stones (from human gallbladder) or a small pebble, cholesterol (0.4 g/kg per day) was added to the diet for 100 days. Non-operated controls were fed the same diet. At the end of the experiment 3 types of liver lesions were found in operated rabbits. The first was characterized by the development of purulent cholecystitis; liver parenchyma showed soft abscesses and lymphoid infiltration. In the second type, cylindrical masses composed of connective tissue were found in the gallbladder and interfered with the outflow of bile from the hepatic ducts; single lobes showed cirrhotic changes. In the third type these cylindrical masses were found in association with stones which had become adherent. Operated rats showed a greater degree of fatty infiltration of the liver than controls and also a markedly higher amount of lipid in the aorta wall. The rabbits with the second and third types of lesions described above had more marked atherosclerosis than did the controls. In a study of 4,335 autopsy protocols, liver involvement was found in 257 cases. In patients with cholelithiasis (without inflammation) atherosclerosis was much more frequent and more pronounced than in the control group (persons who died during accidents). In the rest of the cases (calculous and noncalculous cholecystitis, echinococcus,

LIVER AND BILIARY TRACT

malignant neoplasms and cirrhosis of the liver) there was no significant difference in the extent of development of atherosclerosis as compared to control.

- 6802 A NEW Tc^{99m} LABELLED COLLOID IN LIVER SCANNING. (E.) Degrossi, O. (Jose de San Martin Hosp., Buenos Aires, Argentina), J. M. Seeber and H. Gotta. Minerva Nucl. 9(6):424-425, 1965.

Tc^{99m} , a nuclide with a short half life (6 hr.), emits monochromatic gamma radiation without beta emission, and has a high radiochemical purity. In 50 patients the liver was scanned using a new Tc^{99m} -labeled antimony sulfide colloid stabilized with polyvinylpyrrolidone. The colloid appears to be very stable and is rapidly conc. in the liver. Good pictures were obtained in all cases. Liver tumors were readily detected since they did not take up the colloid. The pictures obtained are comparable to those obtained with labeled rose bengal and with labeled albumin colloid.

- 6803 CAUSES AND CONDITIONS CONTRIBUTING TO THE OCCURRENCE OF HEPATIC ABSCESES. (Rus.) Berdykeev, A. M. (Railway Hosp., Ashkhabad Sta., USSR). Vestn. Khir. Grekov. 95(12):31-35, 1965.

From 1948-62, 237 patients with liver abscess were treated in Ashkhabad. The following diseases were found in this group: dysentery, 37%; respiratory diseases, 35.3%; typhus, 32.5%; malaria, 32.5%; other liver diseases, 13.4%; and papataci (phlebotomus) fever, 3.3%. Diarrhea was seen in 120. The causes of the hepatic abscess were as follows: amebiasis, 180; purulent echinococcosis, 12; appendicitis, 10; bacillary dysentery, 5; calculous cholecystitis, 4; Lamblia, 3; and 1 each of osteomyelitis, purulent paraproctitis, follicular angina and trauma. The etiology in 19 cases was unknown. Among 55 women with liver abscess, 4 were pregnant. About 100 patients consumed alcohol. The highest incidence was seen in the summer and fall seasons; incidence was especially high in September. This seasonal distribution is connected with the frequency of gastrointestinal diseases, particularly amebic dysentery.

- 6804 HEREDITARY NONHEMOLYTIC CONJUGATED HYPERBILIRUBINEMIA WITHOUT ABNORMAL LIVER CELL PIGMENTATION. A FAMILY STUDY. (E.) Pereira Lima, J. E. (Catholic Sch. Med., Porto Alegre, Brazil), E. Utz and I. Roisenberg. Am. J. Med. 40(4):628-633, 1966.

Chronic, nonhemolytic jaundice without signs of abnormal liver cell pigmentation (Rotor syndrome) was diagnosed in 2 sisters and 1 brother; 2 of the siblings were asymptomatic. The parents and the maternal grandparents of these patients were first cousins. Five other living siblings, their children, the 2 children of 1 of the affected siblings, both parents, and other relatives (39 of 72 relatives in 6 generations were examined) were clinically normal. Serum bilirubin levels, determined in 23 of the relatives, were normal. The affected subjects showed hyperbilirubinemia, with free bilirubin predominating in 2 cases and conjugated bilirubin in the third. The 45-min. sulfobromophthalein retention in these patients reached 31-47%, but other hematological data were normal. These symptoms are compared to the Dubin-Johnson syndrome, in which abnormal liver cell pigmentation is present. It is concluded that the Rotor syndrome in this family was transmitted by an autosomal recessive gene.

- 6805 SERUM, LIVER AND BILE TRANSAMINASES DURING EXTRAHEPATIC BILIARY OBSTRUCTION IN THE RAT. (E.) Bengmark, S. (U. Goteborg, Sweden), Y. Edlund and R. Olsson. Acta Hepatosplen. (Stuttgart) 13(2):84-88, 1966.

Thirty female, adult Sprague-Dawley rats were subjected to division of the hepatic duct (except controls). The ligature was applied just proximal to the minute pancreatic ducts that open at intervals into the distal part of the hepatic duct. Studies were performed 1, 2, 4 and 6 days after ligation. Serum glutamic-oxalacetic and serum glutamic pyruvic transaminases rose markedly after 1 and 2 days with

LIVER AND BILIARY TRACT

return to normal, or near-normal values by day 4. In the liver there were no statistically significant changes in glutamic oxalacetic transaminase activity, but liver glutamic-pyruvic transaminase activity began to decrease to subnormal values after 2 days of obstruction. Bile samples were not obtainable on days 1 and 2. Four and 6 days after obstruction, both transaminases in bile showed some increase in activity.

- 6806 ACCESSORY PORTAL SYSTEM IN BLOOD SUPPLY OF THE LIVER IN SCHISTOSOMIASIS. (SYMMERS' FIBROSIS.) (Por.) Magalhães, A., Jr. (Endemias Rurais Nat. Inst., Recife, Brazil) and E. Coutinho-Abath. Rev. Inst. Med. Trop. S. Paulo 8(1):30-36, 1966.

Vascularization of the liver in Symmers' fibrosis (which represents the final stage in the change of the liver due to infestation with Schistosoma mansoni) was studied by examination of liver biopsy specimens from 25 young patients with S. mansoni who were subjected to splenectomy for treatment of congestive splenomegaly. A vascular network was found to have developed from the sinusoids located in the subcapsular area of the liver which had previously undergone degenerative and atrophic changes. Such changes initially are caused by obstructive endophlebitis of intrahepatic portal venous branches, which finally develops into the fibrous bands already described in Schistosomiasis due to S. mansoni.

- 6807 INCIDENCE AND EXTENT OF HEMOSIDEROSIS OF THE LIVER AND OTHER ORGANS OBSERVED AT AUTOPSY, WITH QUANTITATIVE CHEMICAL DATA ON THE PRESENCE OF IRON IN THE LIVER. (It.) Weber, G. (U. Colorado, Denver), G. Mincione, R. A. MacDonald and G. S. Pechet. Arch. De Vecchi Anat. Pat. 45(2):409-436, 1965.

Histological investigation of the liver and other organs obtained from 100 randomly selected autopsy cases (13 of which had prior hepatic or gastrointestinal diseases) revealed the presence of hepatic steatosis in 27, sclerosis in 12, cirrhosis in 4, miscellaneous (metastatic cancer, hepatitis, necrosis, and others) pathology in 15, and no pathology in 42. Hemosiderin was found (Perls' method) in 73% of the cases; deposits were slight in 51 cases and abundant in 22; pigment was localized in the hepatocyte in 35, in Kupffer cells in 11, and in both in 27. Deposits were more frequent in women (42%) than in men (22%). Particularly abundant quantities were observed in the liver of cirrhotic patients; pigment was present in 11 of 12 cases with sclerosis, 19 of 27 with steatosis, and 30 of 42 normal livers. Iron determinations (Scott method) showed mean values of 88-119 mg/100 g of dry organ wt. in hemosiderin-containing livers and 32-41 mg/100 g in livers without hemosiderin. Hemosiderin was found in the pancreas of 11% of the 54 cases investigated.

- 6808 VARIOUS ASPECTS OF BLOOD COAGULATION IN PATIENTS WITH HEPATIC DISEASE. CORRELATION WITH FUNCTIONAL HEPATIC DAMAGE AND CHOLESTASIS. (It.) Coccheri, S. (U. Bologna, Italy), P. Gennari, P. Fiorentini and L. Lodi. Gior. Clin. Med. 46(12):1205-1225, 1965.

Blood coagulation tests were performed in 105 patients with various hepatic diseases (sclerosis 22, hepatitis 20, cirrhosis 19, chronic hepatocholangitis 17, steatosis 12, obstructive jaundice 7, subsequent to cancer of blood diseases 5, primary biliary cirrhosis 3). Both Quick's test and Owren's thrombotest showed significant correlation with the extent of impaired liver function and with cholestasis; the thrombotest was more sensitive. In 30 patients with similar liver diseases, total plasma thromboplastin activity (Hicks and Pitney method) was significantly lowered with results suggesting correlation with the degree of liver damage but not with that of cholestasis. Calculation of statistical data revealed that, unlike the Quick and Owren tests which are influenced in direct proportion to the degree of both hepatic damage and cholestasis, plasma thromboplastin activity is decreased as hepatocellular damage increases and is only slightly influenced by the presence or degree of cholestasis. Thus, determination of plasma thromboplastin activity is of great value in evaluating the degree of hepatic damage.

LIVER AND BILIARY TRACT

- 6809 III. DOSAGE AND DIFFERENTIATION OF URINARY AMINO ACIDS IN NORMAL DOGS AND DOGS SUBJECTED TO PORTACAVAL END-TO-SIDE OR SIDE-TO-SIDE SHUNTS. (Fr.) Ambert, J. P. (U. Paris Fac. Med., Sorbonne), C. P  chery, P. Moukhtar, E. Housset and L. Hartmann. Ann. Biol. Clin. (Paris) 24(1-2): 51-61, 1966.

Dosage and differentiation of urinary amino acids by electrophoresis at pH 5.4, thin layer chromatography, and electrochromatography were performed in dogs subjected to portacaval end-to-side or side-to-side shunts. No significant difference was observed in total amino-aciduria values (mg/liter) in normal dogs (365) or dogs operated at 2-6 wk. (380) or over 6 wk. (410). In operated dogs, the most significant quantitative alteration in amino acid excretion was marked increase in both ethanolamine and γ -aminobutyric acid; moderate increases of glycine, threonine, cystine, proline, glutamic acid, histidine, and methylhistidine were observed as well as decreases in glutamine and serine.

- 6810 PORPHYRIN METABOLISM IN CHRONIC LEAD POISONING AND IN ANEMIA AND LIVER DISEASES NOT ASSOCIATED WITH LEAD POISONING. (It.) Saita, G. (U. Milan, Italy), L. Moreo and G. Croce. Med. Lavoro 57(3):167-174, 1966.

Porphyrin metabolism was studied in 54 patients with liver disease (21 cirrhosis, 10 hepatocellular jaundice, 9 hepatic sclerosis, 7 chronic cholecystitis and 7 obstructive jaundice) and in 42 patients with various types of anemia. Serum δ -aminolevulinic acid levels (normal 0.026 mg/100 ml) were increased in the 2 groups with highest values in patients with hepatocellular jaundice (0.07) and megaloblastic anemia (0.072), and similar to values observed in patients with chronic lead poisoning (0.043). Urinary δ -aminolevulinic acid levels (normal 2.8 mg/24 hr.) were increased in the 2 groups, with highest levels seen in patients with cirrhosis (9.04), hepatocellular jaundice (9.1), and megaloblastic anemia (11.7), but less than those of patients with chronic lead poisoning (15.0) away from their jobs for 1-3 yr. Urinary porphobilinogen levels were normal (1.5 mg/24 hr.) in patients with chronic lead poisoning but increased in patients of the 2 groups, especially in cirrhosis (5.6) and macrocytic anemia (9.4). Uroporphyrin was absent or within normal limits in all patients. Urinary coproporphyrin levels were normal in patients with chronic lead poisoning and slightly increased in some patients with hepatic disease or anemia. RBC levels of protoporphyrin IX (normal 0.055 mg/100 ml) were increased (>0.100) in patients with chronic lead poisoning even 8-10 yr. after leaving their jobs; values were normal or slightly increased in hepatic patients but markedly increased in some patients with anemia (0.111 in hemolytic and non-iron deficiency anemia).

- 6811 EVALUATION OF SOME LABORATORY AIDS FOR THE DIAGNOSIS OF METASTATIC MALIGNANCY OF THE LIVER. (E.) Rajan, K. S. (All India Inst. Med. Sci., New Delhi), S. K. Tikare and B. N. Tandon. Indian J. Med. Res. 54(2):142-147, 1966.

Various diagnostic procedures were carried out in a max. group of 40 patients with suspected metastatic liver carcinoma. Results were compared to findings obtained at laparotomy or from a clinical history suggestive of fulminating liver cancer. Of 40 patients scanned after admin. of ^{131}I -rose bengal or gold ^{198} , there were 21 true positive and 12 correct negative results; the overall diagnostic error (on the basis of 2 false positives and 5 false negatives) was 17.5%. On the basis of admin. of sulfobromophthalein to 25 patients, there were 13 true positives, 3 correct negatives and diagnostic error was 36%. After 32 estimations of alkaline phosphatase, there were 16 true positives, 4 correct negatives and diagnostic error was 37.5%. After 32 estimations each of serum glutamic oxalacetic and serum glutamic pyruvic transaminases, there were, resp., 16 and 10 true positives, 9 and 9 correct negatives, and diagnostic errors were 22% and 40.6%. With the use of all tests, 92.3% of confirmed cases of metastatic carcinoma of the liver could be correctly diagnosed.

LIVER AND BILIARY TRACT

- 6812 CHRONIC BILIARY OBSTRUCTION--HEPATIC CHANGES. AN EXPERIMENTAL STUDY IN DOGS. (E.) Chandra, A. (Govt. Med. Coll., Patiala, India) and R. Dass. Indian J. Surg. 28(2):102-111, 1966.

Chronic obstruction of the bile duct was accomplished in adult mongrel dogs by wrapping the duct with cellophane. In 14 dogs only the common bile duct was subjected to this obstruction, in 4 dogs only the cystic duct was treated and in 5 dogs both ducts were involved. The biliary obstruction produced caused variable degrees of structural changes in the liver. The latter varied with the degree, duration and site of obstruction in the biliary duct system. Common bile duct obstruction when combined with cystic duct obstruction produced more severe changes in the liver than when only one of the two was subjected to obstruction. The cystic duct obstruction, when protracted, produced changes in the liver simulating those of common bile duct obstruction. Spontaneous restoration of the continuity of the common bile duct occurred in 35% of the dogs, usually 9-10 wk. after operations as a result of invagination of the affected area; in these cases the liver did not show complete recovery due to the persistence of intraluminal obstruction.

- 6813 OSTEOPOROSIS, SCURVY, AND SIDEROSIS IN JOHANNESBURG BANTU. (E.) Seftel, H. C. (U. Witwatersrand, Johannesburg, South Africa), C. Malkin, A. Schman, C. Abrahams, S. R. Lynch, R. W. Charlton and T. H. Bothwell. Brit. Med. J. 1(5488):642-646, 1966.

The clinical, radiologic, biochemical, and pathologic features of 32 Bantu subjects with severe spinal osteoporosis are described. Apart from scurvy in 14, their diet was similar to that of the general African population. All subjects, however, consumed large quantities of a local brew which was acid in reaction and which picked up iron from the metal containers in which it was usually prepared. Serum iron was significantly elevated in the osteoporotic patients compared to 41 male in-patients who were being treated for non-infective conditions. The degree of siderosis was assessed further in 16 males and 2 females by histologic study of liver biopsy specimens. Using the criteria described by Bothwell and Bradlow, 17 were found to be severely siderotic and one moderately so. In 2 subjects who came to autopsy, the liver and spleen were enlarged and of a deep rust color. The duodenum, upper part of the jejunum, and abdominal lymph nodes were similarly colored. In one case, the conc. of iron, per 100 g dry wt., was, for liver 3.4%, for spleen 5.7%.

- 6814 LIVER IRON AND DESFERRIOXAMINE-INDUCED URINARY IRON EXCRETION. (E.) Hallberg, L. (Sahlgrenska Hosp., Goteborg, Sweden), L. Hedenberg and A. Weinfeld. Scand. J. Haemat. 3(2):85-98, 1966.

In a continuation of earlier studies, the desferrioxamine-induced urinary iron excretion was measured in subjects in whom surgical biopsy specimens were used to determine liver non-hemin iron. In untreated normals, 24-hr. urinary iron excretion was an av. of 0.07 mg (0.03-0.15). In 10 females, av. urinary iron excretion after desferrioxamine was 0.46 mg; in normal males, av. excretion was 0.70 mg. The difference in mean excretion between males and females was statistically significant. In 2 males with portal cirrhosis the iron excretion was 1.36 and 1.46 mg per 24 hr. There was a very high correlation between the increase of urinary iron excretion after admin. of desferrioxamine on the one hand and the conc. of total non-hemin, ferritin, and hemosiderin iron of the liver on the other.

- 6815 III. TREATMENT OF ENDOGENOUS HEPATIC COMA WITH COENZYME A, α -LIPIC ACID, DIPHOSPHOPYRIDINE NUCLEOTIDE, AND COCARBOXYLASE. (Fr.) Thölen, H. (Saint Antoine Hosp., Paris), A. Colombi and G. Engelhart. Rev. Medicochir. Mal. Foie 41(1):19-30, 1966.

Seventeen patients in hepatic coma of various causes (8 acute or subacute hepatitis; 7 serum hepatitis; 1 purulent cholangiohepatitis; 1 mushroom poisoning) were treated

LIVER AND BILIARY TRACT

with a combination of coenzyme A, thiocctic acid, diphosphopyridine nucleotide, and cocarboxylase; results were postivie in 14 (82%) and negative in 3 (18%; 2 of 3 died after the first infusion). Positive results were seen in 5 of 6 patients in Stage VI, 2 of 4 in Stage III, and 7 of 7 in Stage II of coma. Results of treatment were positive in 11 of 16 patients in hepatic coma as a result of cirrhosis; of these 2 of 3 were in Stage IV, 3 of 4 were in Stage III, and 7 of 9 were in Stage II. Pyruvic acid levels were either decreased or increased as a result of treatment, while acetoin-2,3-butylene glycol levels were decreased after treatment in nearly all patients. Results of histological examination of hepatic tissue before and after treatment are reported for some patients.

- 6816 ANGIOTENSIN RESPONSE IN VARIOUS LIVER DISEASES WITH SPECIAL REFERENCE TO LIVER FUNCTION TESTS. (E.) Bisht, D. B. (Jawaharlal Inst. Postgrad. Med. Ed. Res., Pondicherry, India), K. Uthamalingam and M. B. Pranesh. J. Assn. Physicians India 14(3):159-160, 1966.

Response to a single inj. of angiotensin II (2.5 µg dissolved in 5% glucose) was studied in 45 patients with various liver diseases. Response was classified as ++ (when both systolic and diastolic pressure showed a rise of more than 10 mm Hg), +- (when only systolic pressure rose more than 10 mm Hg), -+ (when only diastolic pressure rose more than 10 mm Hg), -- (when neither pressure rose more than 10 mm Hg), or N.R. (when subsequent fall of more than 10 mm Hg from the resting level was observed). In the authors' series, results were ++, +-, -+, --, and N.R. in 18, 3, 1, 0, and 2, resp., of 22 patients with infectious hepatitis with mild to severe liver damage but not in hepatic coma; 6, 1, 1, 0, and 0, resp., in 8 patients with amebic hepatitis with moderate to gross hepatic enlargement but no appreciable liver damage; 5, 3, 0, 0, and 0, resp., in 8 patients with amebic liver abscess with gross hepatic damage; 5, 2, 0, 0, and 0, resp., in 7 patients with severe malnutrition and anemia with mild to moderate impairment of liver function. Not a single case showed a completely negative response, which is a frequent feature of cirrhosis. Liver function was assayed by standard tests. No correlation was seen between the degree of liver damage and angiotensin response.

- 6817 CLINICAL, HISTOCHEMICAL, AND ULTRASTRUCTURAL STUDIES OF TWO CASES OF THE DUBIN-JOHNSON-ROTOR SYNDROME. (It.) Barone, P. (U. Messina, Italy), C. Inferrera and F. Tigano. Arch. Ital. Anat. Istol. Pat. 39(6):431-478, 1965.

Clinical and histological studies were performed in 2 brothers (age 32 and 24 yr.) with chronic idiopathic jaundice. Data indicates an intermediate stage between the Dubin-Johnson (with hyperpigmentation of the liver) and Rotor (without parenchymal pigmentation) syndromes. Both brothers presented with chronic, benign jaundice, increased blood levels of free and conjugated bilirubin, absence of hemolysis, delayed sulfobromophthalein elimination, lack of visualization of the gallbladder, and slight or lack of impairment of hepatic function. The pigment had staining properties similar to those of lipofuscin. Liver structure was well preserved; no inflammation or obstruction was noted; hepatocyte swelling was more intense 24 hr. after the admin. of sulfobromophthalein. Electron microscopy of liver biopsy specimens revealed the following: reduction in number and swelling of granulations; vesicular degeneration and fragmentation of the endoplasmic reticulum and Golgi apparatus; marked accumulation of both lipofuscin-like and bile-like pigment; reduction in the number of mitochondria with infrequent abnormalities; no appreciable alteration of the microvilli or capillary size.

- 6818 SULFONAMIDES COMPETING WITH BILIRUBIN FOR CONJUGATION TO ALBUMIN. (E.) Josephson, B. (Eriks Hosp., Stockholm, Sweden) and P. Furst. Scand. J. Clin. Lab. Invest. 18(1):51-63, 1966.

LIVER AND BILIARY TRACT

The binding of various sulfonamides and of bilirubin to serum protein or pure albumin was studied by means of ultrafiltration and Sephadex column separation. Sulfamethoxypyridazine and sulfamoxole (sulfadimethyloxazole) were added to sera from premature infants with jaundice and to sera from adult patients with jaundice containing only indirect bilirubin. The above 2 sulfonamides and sulfafurazole (sulfisoxazole) in the same conc. as above were added to normal sera to which bilirubin had been added in precalculated conc. (10-35 mg of bilirubin/100 ml). Upon ultrafiltration, free bilirubin appeared in the ultrafiltrate only if the bilirubin conc. was greater than 20 mg/100 ml and the conc. of the sulfa compound was approx. 25 mg/100 ml or more. Sulfonamides with a low affinity for albumin were not able to replace albumin-bound bilirubin, but sulfamethoxypyridazine, sulfamoxole, and sulfafurazole have a high protein-binding capacity and contain an oxygen atom. Sephadex column separation confirmed these findings. Results suggest that the serum conc. of sulfonamides which might produce kernicterus in premature infants is above 15 mg/100 ml even for sulfonamides with a high affinity for albumin.

Hepatic Injury

- 6902 PHENOBARBITAL-INDUCED FINE STRUCTURAL CHANGES IN RAT LIVER. (E.)
Burger, P. C. (Northwestern U. Sch. Med., Chicago, Ill.) and P. B. Herdson. Am. J. Path. 48(5):793-810, 1966.
Liver structural changes were studied in rats after admin. for 10 days of sodium phenobarbital by various routes (p.o., 0.1% by wt. of diet; 100 mg/kg by gavage daily, 100 mg/kg i.p. daily). All rats showed liver enlargement and hepatic fine structural changes regardless of the route of admin. of the drug or incorporation into the diet. The most striking changes include proliferation of smooth endoplasmic reticulum with concomitant shortening and dispersion of rough endoplasmic cisternae, mitochondrial abnormalities, and the development of myelin figures. The morphologic abnormalities at first affect only central cells, but progressively involve cells further out in the lobule so that after medication for 10 days most of the lobule is involved. Nevertheless, a peripheral zone of normal-looking cells is always present. When the admin. of sodium phenobarbital is combined with the barbiturate potentiator SKF 525-A (β -diethylaminoethyl diphenylpropylacetate HCl), abnormalities of the same type are more extensive after treatment for several days than with phenobarbital alone. SKF 525-A itself causes no detectable abnormalities.
- 6903 ACUTE ETHANOL POISONING AND LIVER METABOLISM. (Ger.) Ammon, H. P. T. (U. Erlangen, Germany), C.-J. Estler and F. Heim. Arch. Inst. Pharmacodyn. 159(2):258-268, 1966.
Within the first 10-30 min. after admin. of ethanol (4.1 mg/g i.v.) to mice, anaerobic carbohydrate breakdown and glycogenolysis in the liver were stimulated. In the next phase (30 min.-10 hr. after treatment), anaerobic carbohydrate breakdown was gradually repressed, as shown by an increase in glycogen, a decreased lactate/pyruvate quotient, and decreased hepatic lactate conc. After alcohol had disappeared from the blood, hepatic lactate and blood glucose were still decreased. High-energy phosphate production in the liver was also suppressed by ethanol. Coenzyme A activity fell by over 90% within the first 2 hr., then rose to control levels after 20 hr. It is suggested that coenzyme A inhibition results from the formation of a semimercaptal between coenzyme A and acetaldehyde.
- 6904 ELECTRON MICROSCOPIC AND MORPHOMETRIC STUDIES OF THE RABBIT LIVER AFTER INTRAVENOUS INJECTION OF ORGANICALLY BOUND COPPER. (Ger.) Wessel, W. (U. Bonn, Germany), P. Gedigk and O. Giersberg. Virchow Arch. Path. Anat. 340(3):206-230, 1966.
In rabbits admin. 2-69 inj. of a copper-ethylenediaminetetraacetate complex over 1-49 wk., the hepatic parenchymal cells took up the copper in a finely dispersed form. In the Kupffer cells, however, copper was taken up in large aggregates and stored in phago-lysosomes which later developed into lysosomes. Storage and digestion took place in the preformed lysosomes, which formed in large numbers a short time after the beginning of treatment. Both the Kupffer cells and the parenchymal cells showed an accumulation of a plasma protein-like substance around the copper particles; this substance became increasingly osmiophilic during storage of the metal particles. Total mitochondrial vol. was increased through the first 40 wk. of the study; at the end of the study, the mitochondria of the severely damaged cells showed a distinct swelling but a decreased vol.
- 6905 CARBOXYL ESTERASE ACTIVITY IN THE LIVER OF DOGS AFTER INTRAVENOUS INJECTION OF SMALL DOSES OF ETHIONINE. (Pol.) Torzecki, Z. (Inst. Path. Anat. Med., Lodz, Poland). Pat. Pol. 17(1):1-7, 1966.
Hepatic carboxyl esterase activity was determined (Holt-Withers method) in 35 dogs following i.v. inj. of ethionine (18-23 mg/kg/day) for 1-21 days. A prompt and marked decrease in enzyme activity was observed in treated animals; after 5 days, no enzyme activity was detected by this method. On day 6, microscopic studies

LIVER AND BILIARY TRACT

Hepatic Injury

revealed clusters of numerous liver cells with high esterase activity and 2-3 nuclei in each cell.

- 6906 THE EFFECT OF HIGH ENERGY LASER PULSES ON THE PRIMATE LIVER. (E.)
Mullins, F. (NCI, Bethesda, Md.), J. P. Minton, R. C. Hoye, J. R. Dearman
and W. B. McKnight. Surg. Gynec. Obstet. 122(4):727-732, 1966.

Surgically accessible areas of the livers of 12 rhesus monkeys were exposed to 5-40 impacts of irradiation from a neodymium laser; the amount of energy delivered ranged from 3,436-29,350 joules. After acute exposure the incision was closed and the animals were allowed to recover; all survived the acute effects. In studies which extended to 8 wk. after exposure, gross and histologic investigation showed that the laser lesions healed rapidly without immediate or delayed hemorrhage or infection. That the healing of the thermal injury was rapid was indicated by the prompt return to normal of liver function studies. There were, however, significant increases in serum glutamic oxalacetic and pyruvic transaminases and especially in serum lactic dehydrogenase. There was mild, transient elevation in serum alkaline phosphatase. These elevations lasted about 2 wk.

- 6907 AUTOAGGRESSION IN HEPATOLOGY. EXPERIMENTAL STUDY. III. EFFECT OF 2,3,5-TRIETHYLENIMINO-p-BENZOQUINONE ON HEPATIC LESIONS CAUSED BY PARENTERAL ADMINISTRATION OF AUTOLOGOUS LIVER HOMOGENATE AND FREUND'S COMPLETE ADJUVANT IN RATS. (It.) Ghetti, A. (U. Florence, Italy), F. Pacini, F. Corradi, A. Panerai, G. Morace and A. Morettini. Riv. Crit. Clin. Med. 65(3):350-355, 1965.

In hepatectomized Sprague-Dawley rats (av. wt. 180 g) treated s.c. with 1 ml/wk. of autologous liver homogenate in Freund's complete adjuvant for 12 wk. beginning 30 days after hepatectomy, concomitant i.p. inj. of 2.5 µg of 2,3,5-triethyleneimino-p-benzoquinone (Trenimon) twice a wk. for the same period prevented the appearance of hepatic lesions which usually occurred following the admin. of the homogenate in Freund's adjuvant. Microscopic findings in Trenimon-treated animals were practically similar to those in control animals subjected to hepatectomy alone. As a possible explanation of the mechanism of this protective action of Trenimon, the authors suggest a specific inhibitory effect on cellular immunity rather than on antibody production, as well as a general antiphlogistic effect. (See also the following abstract.)

- 6908 AUTOAGGRESSION IN HEPATOLOGY. EXPERIMENTAL STUDY. VI. EFFECT OF SPLENECTOMY ON HEPATIC LESIONS CAUSED BY PARENTERAL ADMINISTRATION OF AUTOLOGOUS LIVER HOMOGENATE AND FREUND'S COMPLETE ADJUVANT IN RATS. (It.) Corradi, F. (U. Florence, Italy), F. Pacini, A. Ghetti, A. Panerai, G. Morace and A. Morettini. Riv. Crit. Clin. Med. 65(4):474-486, 1965.

Histological examination of the liver was performed in partially hepatectomized female Sprague-Dawley rats (wt. 150 g) subjected to splenectomy 10 days before (Group I) or 5 wk. after (Group II) s.c. inj. of 0.5 ml of autologous liver homogenate in 0.5 ml of Freund's adjuvant once a wk. for 5-10 wk. In Group I, mortality was 30% (3 of 10 rats); histological findings revealed moderate cellular infiltration at the level of the portal spaces and blood vessels, signs of vacuolar degeneration of hepatocytes, and rare necrotic foci; these changes were similar to those observed in controls treated by autologous liver homogenates and Freund's adjuvant alone. After 5 wk. of treatment, animals of Group II showed a mortality of 50% (5 of 10 rats); the 5 surviving rats developed laminar distortion, foci of necrosis frequently localized in the centrilobular area, and diffuse parvicellular infiltration with tendency toward the formation of aggregates around the portal spaces. Results indicate that splenectomy enhances the hepatotoxic effects of inj. of autologous liver homogenates and Freund's adjuvant observed in the authors' previous experiments, most likely because of the important role of the spleen in antibody formation in the organism. (See also the preceding abstract.)

- 6668 CONTINUOUS FUNCTIONAL ARREST OF THE RECTAL SPHINCTER IN TREATMENT OF PARAPROCTITIS. (Rus.) Zhorov, I. S. and A. A. Blyakher. Vestn. Khir. Grekov. 96(1):64-69, 1966.

A review is presented of 485 cases of paraproctitis (341 acute, 144 chronic). The routine operative technic (early and wide exposure of a pararectal abscess) was used in 198 patients with acute paraproctitis; 90 patients were subjected to operation along with the use of blockade of the rectal sphincter with use of a local anesthetic (in oil) of long duration. Among a group of 114 chronic patients treated surgically, 97 were also subjected to blockade of the sphincter. In terms of late results, among 100 patients subjected to the routine operation, 46 developed fistulas and recurrence. Among the patients with surgery plus rectal sphincter blockade, good results were found in the patients with localized forms of acute paraproctitis. Unsatisfactory results were found mostly in patients with the diffuse forms of paraproctitis. The temporary immobilization of the sphincter in the surgical treatment of acute and chronic paraproctitis is recommended.

- 6669 THE PRUSSIAN-BLUE REACTION IN THE DIAGNOSIS OF PREVIOUS APPENDICITIS. (E.) Howie, J. G. R. (Western Infirm., Glasgow, Scotland). J. Path. Bact. 91(1):85-92, 1966.

In a study of 669 appendices, besides staining of sections with the usual hemalum and eosin, duplicate sections were examined by Perls' prussian-blue technic. The iron content of the appendices was assessed histologically and correlated with the clinical history and operative findings. Compared to a group where there was no history of earlier attacks of appendicitis, there were significant increases in the iron of appendices from patients with a positive past history of appendicitis and in those with "silent" appendicitis. Use of the prussian-blue technic, therefore, in the study of appendices appears to provide a useful index of previous appendicitis, and is of value as a diagnostic and research aid.

- 6670 IRRITABLE COLON SYNDROME IN EGYPTIANS WITH DESCRIPTION OF CASES CONDITIONED BY ANAL FISSURE. (E.) Elsheikh, A. (U. Cairo, Egypt). Gastroenterologia (Basel) 105(3):148-158, 1966.

Among 1,800 patients attending a private clinic for internal diseases, 702 (39%) had irritable colon syndrome. The sex ratio was about equal. The high incidence of irritable colon syndrome in Egypt (probably underestimated) was attributed to the prevalence of anxiety states and to a high incidence of dysentery (amebic and bacillary). There appeared to be a relationship between this syndrome and chronic anal fissure in 36 patients. This was indicated by the fact that block of the pudendal nerves by a long acting local anesthetic, or operative repair, led to relief of symptoms in most patients for a long period of time. A double-blind study indicated that the combined use of an anxiolytic drug (thioridazine, 25 or 10 mg) plus a tablet containing belladonna, ergotamine, and phenobarbital helped control the symptoms.

- 6671 POSTERIOR EXCISIONAL ANO-RECTAL MYOTOMY IN MANAGEMENT OF CHRONIC FAECAL ACCUMULATION. (E.) Bentley, J. F. R. Arch. Dis. Child. 41(216):144-147, 1966.

The technic of posterior excisional anorectal myotomy in the management of chronic fecal accumulation is described. The series of 22 young patients included an infant 6 wk. of age. Two patients had transient postoperative pyrexia. Some transient postoperative anal incontinence may last several wk. Among 7 with normal rectal biopsy histology, 2 boys and a girl have slowly lost their symptoms, but 1 girl remains unchanged. Ten had Hirschsprung's disease: 9 boys and 1 girl. In 9 yr. following operation, one 17-year-old boy has had no disability except for an acute episode of constipation that was precipitated by an attempt to curtail his

LARGE BOWEL

daily dose of paraffin emulsion. In all, 6 of the boys have been treated without major surgery, 3 have spontaneous daily bowel evacuation, but the other 3 continue to use suppositories or a laxative. Five (all boys) showed abnormal myenteric nerve with few ganglion cells. After operation all had a variable period of anal incontinence (up to several wk.) but all except 1 have slowly become clean and continent, though they need the occasional aid of small quantities of evacuants.

- 6672 INTRINSIC NON-PROPULSIVE COLON. (E.) Pagès, R. and B. Duhamel. Arch. Dis. Child. 41(216):151-152, 1966.

Thirteen young patients were observed in a Paris hospital with intestinal obstruction which was associated with intrinsic failure of colonic propulsion. The clinical picture was usually, but not always, associated with extensive lack of colonic ganglia. Histologic examination of the colon (surgical or necropsy specimens) showed some abnormality in the intrinsic nerve in 9 of the 13 patients. Six patients showed impairment of propulsion affecting the entire colon, with consequent gross distention of the small intestine. In 7 patients the defect in propulsion affected more than the left half of the colon. In the series as a whole, 8 patients died and only 5 survived following an extensive operation, despite the fact that proctocolectomy was avoided. There are grounds for including classic Hirschsprung's disease as a "short segment" variant of this syndrome.

In 204 adults and children with ulcerative colitis of recent onset (under 6 mo. in 90%), the av. follow-up period was 4.8 yr. The outcome of the first attack was: remission, 70%; improvement after treatment (unspecified), 16%; surgery, 11%; and death, 3.4%. The overall medical failure rate was 14.7%. The remission rate was highest in those patients with mild first attacks (88%) and only rectal involvement (85%), but only 2 patients had remissions lasting over 7 yr. The severity of the attack was related to the extent of intestinal involvement. The highest incidence of remissions (75%) and the mildest attacks occurred in patients aged 20-59 yr. at onset, but the extent of involvement decreased with age. The prognosis was worst in patients with rapidly developing symptoms. Of 56 patients requiring surgery, 9 died during the early postoperative period and 15 required 26 further operations (none died). The overall mortality rate was 4.0% in mild to moderate and 5.9% in severe first attacks; it increased to 12.2% in patients with substantial intestinal involvement. Mortality during the first attack increased in the older patients (below 20 yr. = 3.7%; 20-59 yr. = 2.3%; over 60 yr. = 21.1%); patients over 60 with severe attacks and extreme involvement had a mortality rate of 83%. The general health of the patients was good or excellent in 98% of the 185 survivors seen at the end of the 12-yr. study period.

- 6743 EARLY HISTOCHEMICAL CHANGES IN ULCERATIVE COLITIS. A LIGHT AND ELECTRON MICROSCOPIC STUDY. (E.) Donnellan, W. L. (Northwestern U. Sch. Med., Chicago, Ill.). Gastroenterology 50(4):519-540, 1966.

Twenty-seven patients (16 males, 11 females) with chronic idiopathic ulcerative colitis were studied by light and electron microscopy. Ages ranged from 15 mo. to 79 yr. Five were receiving corticosteroids at the time of the initial biopsy. Mucosal punch biopsies were taken when possible at 18 cm from the anal margin; in children the distance varied from 10-17 cm. Degeneration of the reticulin fibers of the colonic mucosa and dilation of the subepithelial capillaries are constant and early findings. Later in the course of the disease there is a progressive infiltration of the lamina propria with plasma cells and lymphocytes and, in some cases, with eosinophils and polymorphonuclear cells. Ulceration of the mucosa appears to be directly related to occlusion of the small vessels of the mucosa by platelet agglutination. A possible mechanism for the depletion of reticular collagen in ulcerative colitis is discussed. Steroids do not prevent the changes in collagen which were observed.

- 6744 CARBOHYDRATE INTOLERANCE IN ULCERATIVE COLITIS. (E.) Frazer, A. C. (U. Birmingham, England), C. Hood, R. D. Montgomery, A. G. Davies, R. Schneider, P. A. Carter and J. Goodhart. Lancet 1(7436):503-505, 1966.

Dietary carbohydrate restriction in 3 men with ulcerative colitis produced symptomatic improvement in all 3 cases. All had a history of diarrhea and a sigmoidoscopic confirmation of colitis; 2 were in their initial attacks and the third had colitis of 2 yr. duration. Reduction of total carbohydrate intake produced a decrease in stool vol., lactic acid, and fatty acids; the patients in the initial stages of disease had complete remission of the disease, and the other had a partial remission. Dietary carbohydrates were reintroduced slowly in the cases of complete remission without exacerbation of the symptoms, but the patient with only partial remission remained sensitive to a test dose of dietary lactose (100 g) when tested 3 mo. after the initial study. In this patient, a specific intestinal lactase deficit was later found. The authors suggested that the therapeutic effect of a milk-free diet in ulcerative colitis might be due to lactose intolerance rather than to protein sensitivity.

LARGE BOWEL

Ulcerative Colitis

- 6745 SURGICAL TREATMENT OF ULCERATIVE COLITIS IN CHILDHOOD. (E.) Ehrenpreis, T. (Karolinska Hosp., Stockholm, Sweden). Arch. Dis. Child. 41(216): 137-142, 1966.

There has been a marked increase in children with ulcerative colitis in Stockholm between 1919 and 1953, based on hospital admissions. The 45 children in the present series were 3-16 yr. old at the time of onset, and 9-19 yr. at operation. Operative treatment was as follows: pan-coloproctectomy plus ileostomy (17); colectomy plus ileostomy (9); and colectomy plus anastomosis (19). There were 2 postoperative deaths. There were 49 complications among 27 patients: 18 made an uneventful recovery; 3 children required tracheostomy and respiratory treatment. Fourteen patients had 21 episodes of small bowel obstruction; another common complication was wound rupture or infection (13). In a period of follow-up of 8 mo. to 12 yr. after operation, there have been no late deaths. The majority gained 10-20 kg in wt. during the first 6 mo. Signs of physical and emotional retardation ceased, and development subsequently became adjusted to normal proportions.

- 6746 ARTICULAR COMPLICATIONS OF ULCERATIVE COLITIS. (E.) Wright, V. (U. Leeds Sch. Med., England) and G. Watkinson. Am. J. Proctol. 17(2): 107-115, 1966.

All 269 patients with ulcerative colitis who presented themselves on one particular day were examined by a gastroenterologist and a rheumatologist. Rheumatic complaints were found in 45% of the group. Fifteen patients had ankylosing spondylitis; 31 (11.5%) developed a specific type of arthritis designated colitis arthritis. This disease was distinct from rheumatoid disease clinically, serologically and radiographically. In a radiographic study of the sacro-iliac joints and lumbar spine of 234 patients, 18% of the patients had sacro-ileitis. This represents a highly significant increase in incidence compared with the control population. The sacro-ileitis showed an equal sex incidence while the ankylosing spondylitis affected men more commonly than women.

EXOCRINE PANCREAS

- 6755 THE EFFECT OF IRRADIATION ON THE FINE STRUCTURE AND ENZYMES OF THE DOG PANCREAS. I. SHORT-TERM STUDIES. (E.) Volk, B. W. (Issac Albert Res. Inst., Brooklyn, N. Y.), K. F. Wellmann and A. Lewitan. Am. J. Path. 48(5):721-753, 1966.

After a single large dose (5,000-9,000 r) of roentgen rays to the exteriorized pancreatic remnant in 23 dogs (after pancreatectomy), studies of enzymes and ultra-structure were made at intervals from 30 min. to 21 days. Acinar cells exhibited large numbers of membrane-bound cytoplasmic lesions, with varied patterns. These contained altered cytoplasmic components as well as a variety of pleomorphic electron-dense structures consisting of osmiophilic agranular membranes, vacuoles and granules of varying size and shape. Max. acinar cell damage was manifest 5 to 8 days after treatment. Between the twelfth and 21st days the number of lesions was reduced, although various pleomorphic alterations were still evident. There was also a reduction in the number and size of mature zymogen granules which became more prominent with time. Simultaneously the amount of pancreatic amylase, lipase and leucine aminopeptidase appeared lessened. Islets exhibited moderate degranulation, swelling of mitochondria, distention of endoplasmic reticulum and the appearance of dense bodies in a number of B cells. Several A cells displayed cystic dilatation of the endoplasmic reticulum, deposition of a finely granular intracytoplasmic material and swelling of mitochondria. In contrast to the acinar cells the alterations in islet cells became more conspicuous near the end of the experimental period. Despite the B cell changes daily blood sugar levels and glucose tolerance tests maintained normal values.

- 6756 HYPOGLYCEMIA DUE TO OBSTRUCTION OF PANCREATIC EXCRETORY DUCTS BY CARCINOMA. (E.) McBee, J. W. (2002 Holcombe Blvd., Houston, Texas), F. L. Lanza and E. E. Erickson. Arch. Path. (Chicago) 81(4):287-291, 1966.

Case histories are presented for 2 men (a 43-year-old Caucasian and 45-year-old Negro) who died in a state of severe hypoglycemia. Diabetes had been diagnosed in the latter but could not be established in the former. At autopsy, both had a well-differentiated columnar cell adenocarcinoma of the head of the pancreas. In these cases there was apparent obstruction of the pancreatic excretory ducts with subsequent atrophy of the acinar tissue distal to the lesion and hyperplasia and neoformation of islet tissue. A probable mechanism for these changes is reviewed.

- 6757 THE PATTERN OF PAROTID GLAND SECRETION IN CYSTIC FIBROSIS OF THE PANCREAS. (E.) Marmar, J. (Child. Hosp., Philadelphia, Pa.), G. J. Barbero and M. S. Sibinga. Gastroenterology 50(4):551-556, 1966.

Subjects studied were 12 children with cystic fibrosis of the pancreas and 13 healthy school children. Parotid saliva was collected by placing a Lashley cup over the papilla of Stenson's duct. Reflex salivation was stimulated by sucking an orange-flavored lozenge. Parasympathomimetic stimulation was obtained by s.c. inj. of methacholine chloride (2.25 mg). Flow rates and sodium, potassium, chloride, and calcium conc. were determined for separate collection periods. Secretory rates in patients with cystic fibrosis were elevated under all circumstances. With reflex stimulation and in the pooled sample after methacholine stimulation sodium was significantly elevated in cystic fibrosis patients. Calcium conc. were not elevated after reflex stimulation but were after methacholine stimulation. Calcium excretion was found to become relatively more elevated as secretion proceeded.

- 6758 PREGNANCY IN CYSTIC FIBROSIS OF THE PANCREAS. (E.) Grand, R. J. (NIH, Bethesda, Md.), R. C. Talamo, P. A. di Sant'Agnese and R.H. Schwartz. J.A.M.A. 195(12):993-1000, 1966.

EXOCRINE PANCREAS

Two case histories are presented of cystic fibrosis patients who became pregnant. Disease was diagnosed at ages 18 and 23 yr. A white woman bore 2 normal children. The second patient, a Negro, suffered progressive pulmonary decompensation during and following pregnancy. The patient precipitously delivered a macerated, still-born male infant. The respiratory decompensation did not respond adequately to therapy and patient died on day 11 of her hospital admission. By questionnaire, a total of 8 other patients with cystic fibrosis were found who had been pregnant. Of the entire 10, a total of 5 showed pulmonary decompensation associated with pregnancy; 2 of these died in the postpartum period. There were 2 cases of overt diabetes mellitus which were well-documented prior to pregnancy. There were 4 premature living, and 1 stillborn fetuses. The 11 living infants of the 13 pregnancies are currently free of the clinical manifestations of cystic fibrosis.

- 6759 INFLUENCE OF A FAT DIET ON THE MORPHOLOGY AND FUNCTION OF THE EXOCRINE PANCREAS. (EXPERIMENTAL STUDIES.) (It.) Fontana, G. (U. Bologna, Italy). Riv. Pat. Clin. 20(10):505-529, 1965.
- Morphological and functional studies of the exocrine pancreas were performed in male Sprague-Dawley rats fed balanced, high-fat, or high-fat and high-protein diets. At electron microscopy, rats fed high-fat diets showed changes in pancreatic acinar cells which consisted of a decrease in zymogen granules, mitochondrial swelling, and dilatation of the endoplasmic reticulum with reduction in the number of ribosomes; lipid accumulation was observed in endothelial and acinar cells and in the capillary lumen; marked decrease in pancreatic amylase, lipase, and trypsin levels was also observed. Changes were more marked after 10 days of feeding than after 6 days. Upon return to a balanced diet after 10 days of high-fat diet, most of the morphological alterations were absent but pancreatic enzyme levels were still decreased. In rats fed a high-fat and high-protein diet, acinar cells failed to show changes in mitochondria and endoplasmic reticulum, although fat accumulation was still significant; initial decrease in pancreatic amylase, and subsequent decrease in lipase activity, were observed. Upon return to balanced diet after 10 days of high-fat and high-protein diet, the acinar cells of the pancreas were normal, indicating that the morphological changes induced by this type of diet are reversible.

Pancreatitis

- 6766 ACUTE PANCREATITIS. (E.) McCollum, J. K. (Newcastle Gen. Hosp., Newcastle-Upon-Tyne, England). J. Indian Med. Prof. 12(12):5664-5666, 1966. During a 10-yr. period after 1954, acute pancreatitis was diagnosed in 31 patients: 27 females and 4 males. The av. age at onset of the acute illness was 64 yr. Seven were subjected to laparotomy after recovery from the acute pancreatitis; gallbladder stones were removed in all instances. Three patients have died; 1 died 15 days after laparotomy. A second died 7 yr. after the acute attack. The third died in acute circulatory failure within 24 hr. of the onset of acute pancreatitis. Patients have been followed from 1-9 yr. (av. 5 yr. and 2 mo.). In 14 patients who had no evidence of biliary tract disease before the acute episode, 13 have survived and none have had any subsequent significant abdominal disability. There have been 12 survivors in a group of 14 with abnormality in the biliary tract. Seven have had operations which included choledochotomy and dilatation of the sphincter of Oddi and 6 of these 7 have had no further disability. In one, recurrent pain and jaundice have necessitated re-exploration of the common bile duct, removal of biliary gravel, and repeat dilatation of the lower end of the duct. Two of 5 patients in this group have required readmission because of further episodes of acute pancreatitis.
- 6767 TREATMENT OF CHRONIC PANCREATITIS. (Fr.) White, T. T. (U. Washington Sch. Med., Seattle). Lyon Chir. 61(6):801-814, 1965. Roux-Y side-to-side pancreaticojejunostomy was performed in 15 patients with chronic pancreatitis (13 of alcoholic origin); pain relief lasting 1-6 yr. was observed in 12 of 15 patients; of the 3 failures, 2 were among alcoholic patients and 1 was in a non-alcoholic patient. Although steatorrhea was not improved by this method, diabetes was improved postoperatively in 2 patients. Among patients with chronic pancreatitis of alcoholic origin treated by other methods, failure occurred in 5 of 5 patients treated by cystoduodenal (3) or cystogastric (2) anastomosis, in 3 of 3 patients treated by splanchnicectomy or splanchnic block (effective only in non-alcoholic patients where biliary pathology had been treated), and in 6 of 6 patients treated by sphincterotomy and pancreatic duct drainage. Pancreatic resection using the modified Mallet-Guy technic is indicated in cases of failure of anastomosis or splanchnicectomy.
- 6768 THERAPEUTIC TRIALS WITH EPSILON-AMINOCAPROIC ACID IN EXPERIMENTAL ACUTE PANCREATITIS. (Sp.) Linares, C. A. (Ramos Mejia Hosp., Buenos Aires, Argentina) and C. J. L. Morel. Rev. Argent. Cir. 9(1):13-15, 1965. Acute pancreatitis was induced by a method described in the following abstract in 30 dogs (wt. 10-30 kg); 15 of the dogs also received i.v. inj. of ϵ -aminocaproic acid (500 mg/kg/day in 3 divided doses) for 4 days. Histological examination revealed no significant therapeutic effect in treated dogs as compared to controls. Among treated animals, however, 2 survived and 4 died later (96-168 hr.) than those in the control group. Serum amylase levels (Somogyi method) were higher (166%) in treated animals than in controls (37%). Although some protective action may be due to the antifibrinolytic effect of ϵ -aminocaproic acid, the authors feel that it is not enough to prevent death.
- 6769 EXPERIMENTAL INDUCTION OF ACUTE PANCREATITIS IN THE DOG BY CONNECTION OF THE COMMON BILE DUCT TO THE PRINCIPAL PANCREATIC DUCT. (Sp.) Linares, C. (Ramos Mejia Hosp., Buenos Aires, Brazil), G. Faraj Cualli and C. J. L. Morel. Rev. Argent. Cir. 9(1):16-18, 1965. A technic is described for the establishment of a biliopancreatic communication by means of a polyethylene catheter. Ten mongrel dogs treated this way died of acute pancreatitis in 56-120 hr. Serum amylase levels (Somogyi method) were 80% higher in operated animals than in controls. Histological studies of the pancreas revealed a typical picture of acute pancreatitis with predominance of necrosis and hemorrhage.

In some animals bile pigment was found in the pancreatic duct. No significant changes were observed in the gallbladder or bile ducts, while the liver showed moderate congestion of the portal and centrilobular spaces. (See also the preceding and following abstracts.)

- 6770 EFFECTS OF ANASTOMOSIS OF THE GALLBLADDER WITH THE PRINCIPAL PANCREATIC DUCT IN DOGS. (Sp.) Faraj Cualli, G. (Ramos Mejia Hosp., Buenos Aires, Argentina), C. Linares and C. J. L. Morel. Rev. Argent. Cir. 9(1):23-26, 1965.

Of 10 dogs in which the gallbladder was connected to the pancreatic duct by means of a polyethylene catheter, all survived and 5 were sacrificed 35-60 days after surgery; no alterations of the liver, pancreas, or biliary tract were observed. Ten other dogs were subjected to the same surgical procedure as above in addition to section and ligation of the common bile duct; all animals died 3-6 days after surgery; histological examination of the pancreas revealed intense necrotico-hemorrhagic pancreatitis. Five other dogs treated by gallbladder-pancreatic duct anastomosis in association with delayed common bile duct obstruction (induced by constriction through a polyethylene catheter) died 4-6 days after surgery; histological examination of the pancreas revealed a picture of acute pancreatitis with necrosis and hemorrhage similar to that of the previous group. Results indicate that mere passage of pancreatic juice through the biliary tract does not cause inflammatory or degenerative changes, whereas the presence of bile in the pancreas causes necrotic and hemorrhagic lesions of this organ. (See also the preceding two abstracts.)

- 6771 SERUM TRYPSIN ACTIVITY (ARGININE METHYL ESTERASE). ITS USE IN THE DIAGNOSIS OF CHRONIC PANCREATITIS. (It.) Fontana, G. (U. Bologna, Italy), P. Puddu, F. Faggioli and P. Azzaroli. Gior. Clin. Med. 46(12):1177-1204, 1965.

Serum trypsin activity (based on liberation of methanol by the hydrolysis of p-tosyl-L-arginine methylester hydrochloride (L-TAME) according to the method described by Siegelman *et al.*; normal values 10-50 μ moles of L-TAME/ml/hr.) was determined in 26 patients (age 34-71 yr.) with chronic pancreatitis, most confirmed at biopsy. Basal serum trypsin values were higher than normal in 9 patients; values after stimulation with pancreozymin and secretin were higher than normal in 12 patients. Elevated serum trypsin activity was frequent in recurrent pancreatitis (shortly after acute phase) and in chronic pancreatitis associated with impaired pancreatic secretion. The authors feel that the determination of serum trypsin activity can be a valuable aid in the diagnosis of chronic pancreatitis.

- 6772 ANALYSIS OF RESULTS OF 146 LEFT SPLANCHNICECTOMIES WITH CELIAC GANGLIECTOMY FOR CHRONIC AND RECURRENT PANCREATITIS. (STATISTICS OF P. MALLET-GUY, 1942-1959). (Fr.) White, T.-T. (U. Lyon Fac. Med., France), M. Lawinski, G. Stacher, J. Pangtay Tea and J. Michoulier. Presse Med. 74(13):645-647, 1966.

Among 146 patients subjected to left splanchnicectomy with celiac gangliectomy from 1959-65, a follow-up of 5 yr. was possible in 116. Of 39 patients with predominantly fibrous or calcifying pancreatitis, surgical results were excellent in 11 and good in 8, while 8 others showed some improvement; overall positive results were 69.2%; of 12 failures (30.8%), 3 died from progression of pancreatic disease. Of 44 patients with diffuse parenchymatous pancreatitis in association with biliary lithiasis (choledocholithiasis and cholecystitis excluded), surgical results were excellent in 34 and good in 4, while 3 showed some improvement; overall results were positive in 93.2% and negative in 6.8%. Of 33 patients not included in either of the 2 groups mentioned above, surgical results were excellent in 19 and good in 4, while 6 others showed some improvement; overall results were positive in 87.9% and negative in 12.1% (1 patient died from progression of disease). Among the 116 patients, associated operations included Kehr drainage (9), cholecystectomy (52), gastric surgery (4),

biliary derivation (20), and splenectomy (1). Total results (116 patients) were positive in 83.6% and negative in 16.4% (15 failures; 4 deaths).

- 6773 PANCREATITIS INDUCED BY THE GRAFT-VERSUS-HOST REACTION. (E.) Walters, M. N-I. (U. Western Australia, Perth). J. Path. Bact. 91(1):65-69, 1966. A suspension of spleen cells from Prince Henry Hospital mice was adjusted to a conc. of 20×10^6 cells/ml. When infant Royal Perth Hospital mice received 0.05 ml of this suspension i.p., by the end of the third wk. they were usually moribund and were sacrificed. Severe granulomatous pancreatitis occurs in the runting syndrome so induced. After glandular necrosis, sheets of lymphocytes and macrophages, arising from the lymphoreticular aggregates of the covering serosa, disseminate as an inflammatory pannus throughout the pancreatic interstitium. Only the degenerating remnants of acini, islets and ductules remain. This type of reaction is considered to have but little etiologic significance as far as human pancreatic disease is concerned.

LIVER AND BILIARY TRACT
GENERAL

- 6785 STUDIES OF SO-CALLED INFILTRATIVE HEPATITIS IN CHILDHOOD. (Ger.) Mahnke, P.-F. (U. Leipzig, Germany) and B. Gantenbein. Zbl. Allg. Path. 108(4): 412-416, 1966.

Five cases of typical infiltrative hepatitis were seen among 200 autopsy liver specimens from children. Characteristic findings included conc. of WBC and lymphocytes such as those frequently seen in connection with inflammatory processes, massed in such a way as to obstruct the hepatic veins, especially the central veins and those which drain the area. All of the children were infants (aged 10 days-4 mo.) and all had died of pneumonia. The primary disorders were pneumonia, myelomeningocele, myelomeningocele with spinal leptomenigitis, peritonitis following intestinal infarct (in a child with umbilical hernia), and mongolism with rectal and anal atresia. The infiltrative hepatitis described was a non-specific, although unusually clearly localized, hepatic reaction to extrahepatic disease.

- 6786 SIGNIFICANCE OF STEROID HORMONES FOR THE DEVELOPMENT OF HYPERBILIRUBINEMIA AND NEONATAL JAUNDICE. (Ger.) Lauritzen, C. (U. Kiel, Germany) and W. D. Lehmann. Zschr. Kinderheilk. 95(2):143-154, 1966.

In 8 normal newborn infants, admin. of estriol, pregnanediol, or cortisone during the first 2 wk. of life caused an increase in serum unconjugated bilirubin, but progesterone had no effect. Estriol, progesterone, cortisone, and pregnanediol, when admin. to nursing mothers, were excreted via the milk and resulted in an increase in serum bilirubin in the infants. Therapeutic doses of prednisolone, dexamethasone, triiodothyronine, dehydroepiandrosterone, and the anabolic steroids 19-nortestosterone phenylpropionate (Durabolin) and 17 α -methandrostenolone acetate (Primobolan) were also without effect; triiodothyronine did not affect the increase in serum bilirubin seen in infants treated simultaneously with estriol. The phenomenon is explained as an effect of competition between these steroids and bilirubin for glucuronosyl transferase in the liver of newborn infants. The high quantities of placental and fetal hormones that must be conjugated and excreted in the first few days of life compete with bilirubin for the conjugating enzyme. This hypothesis was confirmed by another study in newborn infants, showing that serum bilirubin levels were not elevated after admin. of the glucuronide conjugates of estriol, pregnanediol, or deoxycorticosterone.

- 6787 HEPATIC BLOOD FLOW IN HEPATOSPLENIC BILHARZIASIS. (E.) Mousa, A. H. (Cairo U., Egypt), A. A. Atta, A. El Rooby, A. A. El-Garem, M. Saif and A. Zein El-Abdin. J. Trop. Med. Hyg. 69(2):45-50, 1966.

In 60 patients with early or late schistosomiasis, hepatic blood flow (estimated by Au¹⁹⁸ or sulfobromophthalein clearance) was within the normal range in all patients except those who showed extensive collateral circulation. There was a marked negative correlation between hepatic blood flow and intrasplenic pressure in patients with collaterals, but there was no correlation between hepatic blood flow and spleen size in patients with or without collaterals. Maintenance of liver circulation within normal limits may have resulted from an increase in portal pressure (up to a certain limit) and total blood vol. Arterial compensation via the hepatic artery was noted in patients with schistosomiasis, but not in those with true cirrhosis.

- 6788 COLORIMETRIC DETERMINATION OF SERUM GUANASE ACTIVITY. (E.) Caraway, W. T. (McLaren Gen. Hosp., Flint, Mich.). Clin. Chem. 12(4):187-193, 1966.

The method is based on the determination of ammonia (liberated by the deamination of guanine by guanase) by the Berthelot phenate-hypochlorite reaction. The rate of guanine deamination was independent of conc. and linear with time up to 2 hr. Guanase activity was also independent of pH over the range 6.5-8.1. The rate of the guanase reaction was directly proportional to the serum guanase conc.; nominal activity under standard conditions was 38.8 U/1000 ml. Guanase activity rose

LIVER AND BILIARY TRACT

2.4-fold when the incubation temperature was increased from 25° to 37°C; about 10% of the guanase activity was lost when the serum was preincubated for 30 min. at 56° before assay at 37°. The results were reasonably reliable using whole serum, but more reliable with protein-free supernatants. In 39 patients without hepatobiliary disease (including patients with duodenal ulcers and pancreatitis), serum guanase activity was 0-3 U/1000 ml. Serum guanase activity increased parallel to serum glutamic-oxaloacetic transaminase activity in patients with jaundice resulting from acute hepatocellular disease, but was normal in other jaundiced patients with extrahepatic obstruction without secondary hepatocellular involvement. The significance of guanase determination in the differential diagnosis of jaundice is discussed.

- 6789 ROLE OF AZYGOS VENOUS SYSTEM IN THE INVESTIGATION OF PORTAL HYPERTENSION. (E.) Murray, M. J. (U. Minnesota Sch. Med., Minneapolis). Gut 7(1):94-98, 1966.

Studies were conducted in dogs 1-2 mo. after the second of 2 operations in which portal systemic collaterals were prepared and portal hypertension was induced by obstruction of the portal vein to decide if azygos vein catheterization was a useful approach to the study of portal hypertension with collateral flow. Azygos catheterization was found to be both a practical procedure and a reliable indicator of portal pressure. Increased oxygen content of the azygos blood appeared to be a sign of collateral flow. No increase in catecholamine or serotonin in azygos blood could be found but the ammonia content was higher in the animals with collateral flow than in control animals. Using indicator substances instilled into the jejunum the collateral circulation could be readily detected and quantitated crudely by sampling from the azygos and hepatic veins. It would appear that these methods are entirely applicable to humans and preliminary studies in patients with cirrhosis support this hypothesis.

- 6790 ACCIDENTAL LIGATION OF THE HEPATIC ARTERY. (E.) Monafó, W. W., Jr. (4960 Audubon Ave., St. Louis, Mo.), J. L. Ternberg and R. Kempson. Arch. Surg. (Chicago) 92(4):643-652, 1966.

Case reports of 11 adults without significant preexisting hepatic parenchymal disease who had accidental ligation of one of the major divisions of the hepatic artery are presented. The accidents occurred during cholecystectomy or pancreaticoduodenal resection (4 cases each) and once during gastrectomy, nephrectomy, and repair of a hepatic artery aneurysm. Hepatic necrosis was proved by biopsy or autopsy in each of the 8 patients who died and was judged to be the cause of death. Three of the 4 patients who underwent reconstruction of their hepatic artery survived. Detailed postoperative study of hepatic function was performed in four cases. Extreme, sustained elevations of serum glutamic oxalacetic and serum glutamic pyruvic transaminases were observed in those who died of hepatic necrosis. Arterial reconstruction of nonfatal hepatic infarction was associated with a smaller rise in the serum levels of these enzymes followed by a return of them to normal after 5-10 days. Mild bilirubinemia and a delayed rise and fall in the serum alkaline phosphatase were also observed in those who survived.

- 6791 THE LEVEL OF HIGHLY-UNSATURATED FATTY ACIDS IN THE BLOOD SERUM IN CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (Rus.) Velikov, V. K. Ter. Arkh. 38(1):47-50, 1966.

The serum of patients with chronic epithelial hepatitis tended to have a decreased amount of linoleic and arachidonic acids, which, however, was not significant. Linolenic and pentanoic acids remained normal. In patients with liver cirrhosis (55 as a result of chronic epithelial hepatitis) there was a statistically significant decrease of linoleic acid and a less pronounced decrease of the other polyenes. In patients with chronic mesenchymal hepatitis, all of the acids were increased in the serum; this increase was correlated with a high content of cholesterol in most of the patients. Similar results were found also in 4 patients with mechanical jaundice and in 1 patient with xanthomatosis. In one of two patients with subacute

LIVER AND BILIARY TRACT

dystrophy the levels of polyenic acids were markedly increased after recovery; content 6 mo. later was somewhat below normal. It is therefore suggested that the diet of chronic hepatitis patients be supplemented with additional amounts of vegetable oils.

- 6792 PROTEIN CHARACTERISTICS OF SERUM AND BILE ALKALINE PHOSPHATASE. (E.)
Pope, C. E. II (Boston City Hosp., Mass.) and S. R. Cooperband.
Gastroenterology 50(5):631-636, 1966.

Gallbladder bile was obtained from the gallbladders of 15 patients undergoing laparotomy for diseases unrelated to the hepatobiliary tree and from the gallbladders of 31 patients with cholelithiasis or inflammatory disease of the hepatobiliary system. The isozyme pattern was determined by horizontal starch gel electrophoresis. The isozymes of alkaline phosphatase found in the bile do not resemble those found in the serum. Incubation of bile with serum does not convert the serum alkaline phosphatase isozymes to a pattern resembling those found in bile. Ultracentrifugation of serum and bile shows that serum and bile alkaline phosphatase have approx. similar molecular sizes. These findings suggest that bile alkaline phosphatase does not represent an excretion product of serum alkaline phosphatase.

- 6793 THIN LAYER CHROMATOGRAPHY OF SERUM CHOLESTEROL ESTERS IN PATIENTS WITH VARIOUS HEPATIC DISEASES. (It.) Tucci, G. (U. Bologna, Italy), L. Gandolfi, L. Frizziero and O. Masiello. *Rass. Fisiopat. Clin. Ter.* 37(2):114-128, 1965.

Serum cholesterol esters were determined by thin layer chromatography (Zöllner method) in 18 normal subjects and in 33 patients with various liver diseases, including cirrhosis (18), obstructive jaundice (7), acute hepatitis (6), sclerosis (1), and hepatic metastasis from breast cancer (1). Among normal subjects, serum levels were highest for esters of di- (39.4%) and mono-unsaturated (26%) fatty acids. Among patients with hepatic disease, mono-unsaturated fatty acid esters were increased in all groups, with highest levels in patients with biliary cirrhosis (39.4%) and slightly above normal levels in patients with obstructive jaundice (34.3%). Di-unsaturated fatty acid esters were significantly decreased in patients with acute hepatitis (33%), hepatic cirrhosis (35.7%), and biliary cirrhosis (32.8%). Cirrhosis patients also showed a decrease in esters of tri- and tetra-unsaturated fatty acids. Contrary to other hepatic diseases, obstructive jaundice was usually accompanied by a decrease in saturated fatty acid esters (13.3% as compared to normal values of 17.6%). Results seem to indicate that the insufficient liver is able to utilize better the esters of polyunsaturated fatty acids, and that impaired absorption of fats in various hepatic diseases is not a contributing factor.

- 6794 EFFECT OF LIVER DISEASE UPON STEROID CIRCADIAN RHYTHMS IN MAN. (E.)
Tucci, J. R. (Georgetown U. Sch. Med., Washington, D. C.), R. A. Albacete and M. M. Martin. *Gastroenterology* 50(5):637-644, 1966.

Plasma and urinary unconjugated, plasma conjugated and urinary total 17-hydroxycorticosteroid levels were determined in 6 consecutive 4-hr. periods; the plasma levels were measured at the midpoint of each urine collection. In 11 patients with known liver disease (cirrhosis), plasma unconjugated as well as conjugated 17-hydroxycorticosteroid levels were within the normal range in the morning. Plasma unconjugated 17-hydroxycorticosteroids demonstrated a circadian variation within the broad limits of normal in 4 of 8 patients with liver disease studied. In the remaining 4, peak levels were maintained longer than normal or else the variation was markedly reduced. Plasma conjugated 17-hydroxycorticosteroids showed a slower than normal rise and broader peak resulting in inversion of the normal diurnal rhythm in 6 of the 8 patients investigated. The urinary findings reflected the plasma changes. The 24-hr. excretion of free 17-hydroxycorticosteroids in the urine was significantly greater than in the normal subjects, whereas total 17-hydroxycorticosteroids excretion was reduced.

LIVER AND BILIARY TRACT

- 6795 LIVER PATHOLOGY IN MALNOURISHED NEW GUINEANS. (E.) Bailey, K. V. (Natr. Res. Unit, Kundiawa, Territory of Papua & New Guinea). Med. J. Aust. 1(14):572-575, 1966.

The Chimbu highlanders who form the basis of this report chiefly eat the sweet potato, which supplies over 80% of the calories and 50% of the protein of the diet. In 1961, hospital admissions included the following: kwashiorkor, 43; marasmus 171 (7 mo.-5 yr. 105; 1-6 mo. 66); malnutrition 14 (6-15 yr.). Biopsy and autopsy material revealed mild fatty change which was found in most of the children with kwashiorkor and in about half of the children with marasmus. Fatty change was not seen in the livers of 5 healthy lactating women but occurred in 8 of 17 with nutritional edema. Large, swollen cells with clear, pale-staining cytoplasm and a thickened cell membrane were frequently seen in the specimens, forming sheets with a distinctive mosaic of wire-netting appearance. Portal fibrosis was not seen in children with kwashiorkor but was seen in some children suffering from malnutrition.

- 6796 SPLENOPORTOGRAPHY IN BUDD-CHIARI'S SYNDROME AND DISEASE. (E.) Chudáček, Z. (U. Pilsen Hosp., Czech.). Radiol. Clin. (Basel) 34(4):247-253, 1965. Two cases of Budd-Chiari's syndrome are presented. A 20-year-old woman developed sepsis after abortion, accompanied by hepatomegaly. Roentgenograms showed mild splenomegaly but pronounced hepatomegaly. Splenoportography visualized the vena coronaria ventriculi as well as the venous system of the esophagus. Contrast medium persisted in the splenic vein and its tributaries after it had disappeared from the liver. Ascites developed several days later, the surface of the liver became uneven, and the patient died 14 days after splenoportography. Postmortem examination revealed that the inferior vena cava under the diaphragm was filled with old, de-colored thrombus, under which was found recent stagnation thrombosis. The second case concerned a 16-year-old boy with edema of the lower extremities, ascites, caput medusae, and arterial hypertension. Splenoportography revealed a slightly enlarged spleen, considerably enlarged liver, portal hypertension and normal ramification of the portal vein in the liver. Contrast medium persisted for a long period in the splenic vein, its tributaries and liver. There was incomplete obstruction of the inferior vena cava at the level of T 9 up to L 1. The renal vein on the right side was displaced in a distal direction. A pneumoretroperitoneum verified a tumor of the right adrenal gland.

- 6797 THE ULTRASTRUCTURE OF ACIDOPHILIC "COUNCILMAN-LIKE" BODIES IN THE LIVER. (E.) Klion, F. M. (Mt. Sinai Hosp., New York, N. Y.) and F. Schaffner. Am. J. Path. 48(5):755-767, 1966.

An ultrastructural study is presented of the liver of 5 adults with hepatitis, 2 children with hepatoma, and of auxiliary liver which was transplanted into the pelvis of 3 dogs 6-8 days previously. The acidophilic bodies found apparently represent a form of hepatocellular injury which can occur in species other than man and which does not indicate any specific etiologic agent. The ultrastructure of acidophilic bodies clearly reaffirms their hepatocellular origin since they contain rosettes of particulate glycogen and organelles similar to those in normal hepatocytes. These "Councilman-like" acidophilic bodies constitute entire cells containing condensed hyaloplasm. These are separated from their neighbors and are surrounded by macrophages and may represent a later stage of the so-called "dark cells."

- 6798 CLINICAL EVALUATION OF LIVER SIZE AND HEPATIC SCINTISCAN. (E.) Peternel, W. W. (U. Cincinnati Coll. Med., Ohio), J. W. Schaeffer and L. Schiff. Am. J. Dig. Dis. 11(5):346-350, 1966.

The clinical estimation of liver size was evaluated in 21 adults without known liver disease and 22 with various diseases of the liver. Radioisotope scintiscans were used as a standard of comparison. For liver scintiscans, most patients were given (after thyroid blockade) 150 μ c of ^{131} -rose bengal i.v.; several subjects received a dose of 150 μ c of Au^{198} . It was found that the upper border of liver dullness

LIVER AND BILIARY TRACT

(as delineated by percussion) was almost always too low. The normal liver may frequently extend below the costal margin and the xiphoid process and yet be impalpable.. Percussion offers a more accurate means of estimating the lower border of the normal or the acutely diseased liver. A truer estimation of liver size is obtained in patients with chronic liver disease, presumably because the increased consistency of the organ enhances the detection of its lower border by physical examination.

- 6799 AN EXPERIMENTAL STUDY ON HEMORRHAGIC SHOCK; PARTICULARLY ON PECULIARITY OF SHOCK CAUSED BY HEMORRHAGE FROM THE PORTAL VEIN. (Jap.) Saiki, H. (Kanazawa U. Sch. Med., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 35(2):331-345, 1966.

Groups of dogs were bled from either the portal or femoral vein by two procedures: intermittent withdrawal (5 ml/kg every 30 min.) or continuous withdrawal. Changes related to the general circulation such as arterial and venous pressure, and circulating plasma vol. were similar in all 4 groups of dogs. In contrast to these findings, portal pressure showed a characteristic increase as shock levels were reached by either method of blood withdrawal. Infusion of fluids or the return of blood in this situation resulted in elevation of the pressure. Shortening of survival time, disturbance of liver function and parenchymal impairment of the liver were all more intense in the group in which blood was withdrawn from the portal vein than in the group in which blood was withdrawn from the femoral veins.

- 6800 ARTERIALIZATION OF THE LIVER IN PLACEMENT OF PORTACAVAL ANASTOMOSIS. (Rus.) Khanin, M. N. (Tashkent Inst. Med., USSR), T. G. Mankus, B. S. Sadreddinov, B. I. Kinel, S. M. Prigozhina and E. N. Ostoumova. Pat. Fiziol. Eksp. Ter. 9(6):35-38, 1965.

In a control series of 5 dogs with portacaval anastomosis only, vomiting, loss of wt., and exhaustion were noted. Encephalopathy was observed in 4 of the dogs during the first 10 days; this condition recurred after treatment with glucose or milk plus sugar. These 4 dogs were sacrificed after 4-8 wk. in a condition of extreme exhaustion. Only 1 dog of the 5 was in satisfactory condition 3 mo. after surgery. None of 6 dogs subjected to portacaval anastomosis but with anastomosis of the splenic artery with the proximal end of the portal vein showed encephalopathy or vomiting after feeding; 3 days after feeding with meat nearly all the dogs ate poorly. Three showed loss of wt., 2 gained wt. and 1 showed no change. One dog died 4.5 mo. after surgery but the cause of death could not be determined.

- 6801 EFFECT OF LIVER AND BILIARY TRACT DISEASES ON THE DEVELOPMENT OF ATHEROSCLEROSIS. (Rus.) Lukash, N. V. (Crimean Inst. Med., Simferopol, USSR) and R. A. Kaganovich. Arkh. Pat. 27(12):63-65, 1965.

Fifteen days after insertion into the gallbladder of rabbits of 3 cholesterol stones (from human gallbladder) or a small pebble, cholesterol (0.4 g/kg per day) was added to the diet for 100 days. Non-operated controls were fed the same diet. At the end of the experiment 3 types of liver lesions were found in operated rabbits. The first was characterized by the development of purulent cholecystitis; liver parenchyma showed soft abscesses and lymphoid infiltration. In the second type, cylindrical masses composed of connective tissue were found in the gallbladder and interfered with the outflow of bile from the hepatic ducts; single lobes showed cirrhotic changes. In the third type these cylindrical masses were found in association with stones which had become adherent. Operated rats showed a greater degree of fatty infiltration of the liver than controls and also a markedly higher amount of lipid in the aorta wall. The rabbits with the second and third types of lesions described above had more marked atherosclerosis than did the controls. In a study of 4,335 autopsy protocols, liver involvement was found in 257 cases. In patients with cholelithiasis (without inflammation) atherosclerosis was much more frequent and more pronounced than in the control group (persons who died during accidents). In the rest of the cases (calculous and noncalculous cholecystitis, echinococcus,

LIVER AND BILIARY TRACT

malignant neoplasms and cirrhosis of the liver) there was no significant difference in the extent of development of atherosclerosis as compared to control.

- 6802 A NEW Tc^{99m} LABELLED COLLOID IN LIVER SCANNING. (E.) Degrossi, O. (Jose de San Martín Hosp., Buenos Aires, Argentina), J. M. Seeber and H. Gotta. *Minerva Nucl.* 9(6):424-425, 1965.

Tc^{99m}, a nuclide with a short half life (6 hr.), emits monochromatic gamma radiation without beta emission, and has a high radiochemical purity. In 50 patients the liver was scanned using a new Tc^{99m}-labeled antimony sulfide colloid stabilized with polyvinylpyrrolidone. The colloid appears to be very stable and is rapidly conc. in the liver. Good pictures were obtained in all cases. Liver tumors were readily detected since they did not take up the colloid. The pictures obtained are comparable to those obtained with labeled rose bengal and with labeled albumin colloid.

- 6803 CAUSES AND CONDITIONS CONTRIBUTING TO THE OCCURRENCE OF HEPATIC ABSCESES. (Rus.) Berdykeev, A. M. (Railway Hosp., Ashkhabad Sta., USSR). *Vestn. Khir. Grekov.* 95(12):31-35, 1965.

From 1948-62, 237 patients with liver abscess were treated in Ashkhabad. The following diseases were found in this group: dysentery, 37%; respiratory diseases, 35.3%; typhus, 32.5%; malaria, 32.5%; other liver diseases, 13.4%; and papataci (phlebotomus) fever, 3.3%. Diarrhea was seen in 120. The causes of the hepatic abscess were as follows: amebiasis, 180; purulent echinococcosis, 12; appendicitis, 10; bacillary dysentery, 5; calculous cholecystitis, 4; *Lamblia*, 3; and 1 each of osteomyelitis, purulent paraproctitis, follicular angina and trauma. The etiology in 19 cases was unknown. Among 55 women with liver abscess, 4 were pregnant. About 100 patients consumed alcohol. The highest incidence was seen in the summer and fall seasons; incidence was especially high in September. This seasonal distribution is connected with the frequency of gastrointestinal diseases, particularly amebic dysentery.

- 6804 HEREDITARY NONHEMOLYTIC CONJUGATED HYPERBILIRUBINEMIA WITHOUT ABNORMAL LIVER CELL PIGMENTATION. A FAMILY STUDY. (E.) Pereira Lima, J. E. (Catholic Sch. Med., Porto Alegre, Brazil), E. Utz and I. Roisenberg. *Am. J. Med.* 40(4):628-633, 1966.

Chronic, nonhemolytic jaundice without signs of abnormal liver cell pigmentation (Rotor syndrome) was diagnosed in 2 sisters and 1 brother; 2 of the siblings were asymptomatic. The parents and the maternal grandparents of these patients were first cousins. Five other living siblings, their children, the 2 children of 1 of the affected siblings, both parents, and other relatives (39 of 72 relatives in 6 generations were examined) were clinically normal. Serum bilirubin levels, determined in 23 of the relatives, were normal. The affected subjects showed hyperbilirubinemia, with free bilirubin predominating in 2 cases and conjugated bilirubin in the third. The 45-min. sulfobromophthalein retention in these patients reached 31-47%, but other hematological data were normal. These symptoms are compared to the Dubin-Johnson syndrome, in which abnormal liver cell pigmentation is present. It is concluded that the Rotor syndrome in this family was transmitted by an autosomal recessive gene.

- 6805 SERUM, LIVER AND BILE TRANSAMINASES DURING EXTRAHEPATIC BILIARY OBSTRUCTION IN THE RAT. (E.) Bengmark, S. (U. Goteborg, Sweden), Y. Edlund and R. Olsson. *Acta Hepatosplen. (Stuttgart)* 13(2):84-88, 1966.

Thirty female, adult Sprague-Dawley rats were subjected to division of the hepatic duct (except controls). The ligature was applied just proximal to the minute pancreatic ducts that open at intervals into the distal part of the hepatic duct. Studies were performed 1, 2, 4 and 6 days after ligation. Serum glutamic-oxalacetic and serum glutamic pyruvic transaminases rose markedly after 1 and 2 days with

LIVER AND BILIARY TRACT

return to normal, or near-normal values by day 4. In the liver there were no statistically significant changes in glutamic oxalacetic transaminase activity, but liver glutamic-pyruvic transaminase activity began to decrease to subnormal values after 2 days of obstruction. Bile samples were not obtainable on days 1 and 2. Four and 6 days after obstruction, both transaminases in bile showed some increase in activity.

- 6806 ACCESSORY PORTAL SYSTEM IN BLOOD SUPPLY OF THE LIVER IN SCHISTOSOMIASIS. (SYMMERS' FIBROSIS.) (Por.) Magalhães, A., Jr. (Endemias Rurais Nat. Inst., Recife, Brazil) and E. Coutinho-Abath. Rev. Inst. Med. Trop. S. Paulo 8(1):30-36, 1966.

Vascularization of the liver in Symmers' fibrosis (which represents the final stage in the change of the liver due to infestation with Schistosoma mansoni) was studied by examination of liver biopsy specimens from 25 young patients with S. mansoni who were subjected to splenectomy for treatment of congestive splenomegaly. A vascular network was found to have developed from the sinusoids located in the subcapsular area of the liver which had previously undergone degenerative and atrophic changes. Such changes initially are caused by obstructive endophlebitis of intrahepatic portal venous branches, which finally develops into the fibrous bands already described in Schistosomiasis due to S. mansoni.

- 6807 INCIDENCE AND EXTENT OF HEMOSIDEROSIS OF THE LIVER AND OTHER ORGANS OBSERVED AT AUTOPSY, WITH QUANTITATIVE CHEMICAL DATA ON THE PRESENCE OF IRON IN THE LIVER. (It.) Weber, G. (U. Colorado, Denver), G. Mincione, R. A. MacDonald and G. S. Pechet. Arch. De Vecchi Anat. Pat. 45(2):409-436, 1965.

Histological investigation of the liver and other organs obtained from 100 randomly selected autopsy cases (13 of which had prior hepatic or gastrointestinal diseases) revealed the presence of hepatic steatosis in 27, sclerosis in 12, cirrhosis in 4, miscellaneous (metastatic cancer, hepatitis, necrosis, and others) pathology in 15, and no pathology in 42. Hemosiderin was found (Perls' method) in 73% of the cases; deposits were slight in 51 cases and abundant in 22; pigment was localized in the hepatocyte in 35, in Kupffer cells in 11, and in both in 27. Deposits were more frequent in women (42%) than in men (22%). Particularly abundant quantities were observed in the liver of cirrhotic patients; pigment was present in 11 of 12 cases with sclerosis, 19 of 27 with steatosis, and 30 of 42 normal livers. Iron determinations (Scott method) showed mean values of 88-119 mg/100 g of dry organ wt. in hemosiderin-containing livers and 32-41 mg/100 g in livers without hemosiderin. Hemosiderin was found in the pancreas of 11% of the 54 cases investigated.

- 6808 VARIOUS ASPECTS OF BLOOD COAGULATION IN PATIENTS WITH HEPATIC DISEASE. CORRELATION WITH FUNCTIONAL HEPATIC DAMAGE AND CHOLESTASIS. (It.) Coccheri, S. (U. Bologna, Italy), P. Gennari, P. Fiorentini and L. Lodi. Gior. Clin. Med. 46(12):1205-1225, 1965.

Blood coagulation tests were performed in 105 patients with various hepatic diseases (sclerosis 22, hepatitis 20, cirrhosis 19, chronic hepatocholangitis 17, steatosis 12, obstructive jaundice 7, subsequent to cancer of blood diseases 5, primary biliary cirrhosis 3). Both Quick's test and Owren's thrombotest showed significant correlation with the extent of impaired liver function and with cholestasis; the thrombotest was more sensitive. In 30 patients with similar liver diseases, total plasma thromboplastin activity (Hicks and Pitney method) was significantly lowered with results suggesting correlation with the degree of liver damage but not with that of cholestasis. Calculation of statistical data revealed that, unlike the Quick and Owren tests which are influenced in direct proportion to the degree of both hepatic damage and cholestasis, plasma thromboplastin activity is decreased as hepatocellular damage increases and is only slightly influenced by the presence or degree of cholestasis. Thus, determination of plasma thromboplastin activity is of great value in evaluating the degree of hepatic damage.

LIVER AND BILIARY TRACT

- 6809 III. DOSAGE AND DIFFERENTIATION OF URINARY AMINO ACIDS IN NORMAL DOGS AND DOGS SUBJECTED TO PORTACAVAL END-TO-SIDE OR SIDE-TO-SIDE SHUNTS. (Fr.) Ambert, J. P. (U. Paris Fac. Med., Sorbonne), C. Péchery, P. Moukhtar, E. Housset and L. Hartmann. Ann. Biol. Clin. (Paris) 24(1-2): 51-61, 1966.

Dosage and differentiation of urinary amino acids by electrophoresis at pH 5.4, thin layer chromatography, and electrochromatography were performed in dogs subjected to portacaval end-to-side or side-to-side shunts. No significant difference was observed in total amino-aciduria values (mg/liter) in normal dogs (365) or dogs operated at 2-6 wk. (380) or over 6 wk. (410). In operated dogs, the most significant quantitative alteration in amino acid excretion was marked increase in both ethanolamine and γ -aminobutyric acid; moderate increases of glycine, threonine, cystine, proline, glutamic acid, histidine, and methylhistidine were observed as well as decreases in glutamine and serine.

- 6810 PORPHYRIN METABOLISM IN CHRONIC LEAD POISONING AND IN ANEMIA AND LIVER DISEASES NOT ASSOCIATED WITH LEAD POISONING. (It.) Saita, G. (U. Milan, Italy), L. Moreo and G. Croce. Med. Lavoro 57(3):167-174, 1966.

Porphyrin metabolism was studied in 54 patients with liver disease (21 cirrhosis, 10 hepatocellular jaundice, 9 hepatic sclerosis, 7 chronic cholecystitis and 7 obstructive jaundice) and in 42 patients with various types of anemia. Serum δ -aminolevulinic acid levels (normal 0.026 mg/100 ml) were increased in the 2 groups with highest values in patients with hepatocellular jaundice (0.07) and megaloblastic anemia (0.072), and similar to values observed in patients with chronic lead poisoning (0.043). Urinary δ -aminolevulinic acid levels (normal 2.8 mg/24 hr.) were increased in the 2 groups, with highest levels seen in patients with cirrhosis (9.04), hepatocellular jaundice (9.1), and megaloblastic anemia (11.7), but less than those of patients with chronic lead poisoning (15.0) away from their jobs for 1-3 yr. Urinary porphobilinogen levels were normal (1.5 mg/24 hr.) in patients with chronic lead poisoning but increased in patients of the 2 groups, especially in cirrhosis (5.6) and macrocytic anemia (9.4). Uroporphyrin was absent or within normal limits in all patients. Urinary coproporphyrin levels were normal in patients with chronic lead poisoning and slightly increased in some patients with hepatic disease or anemia. RBC levels of protoporphyrin IX (normal 0.055 mg/100 ml) were increased (>0.100) in patients with chronic lead poisoning even 8-10 yr. after leaving their jobs; values were normal or slightly increased in hepatic patients but markedly increased in some patients with anemia (0.111 in hemolytic and non-iron deficiency anemia).

- 6811 EVALUATION OF SOME LABORATORY AIDS FOR THE DIAGNOSIS OF METASTATIC MALIGNANCY OF THE LIVER. (E.) Rajan, K. S. (All India Inst. Med. Sci., New Delhi), S. K. Tikare and B. N. Tandon. Indian J. Med. Res. 54(2):142-147, 1966.

Various diagnostic procedures were carried out in a max. group of 40 patients with suspected metastatic liver carcinoma. Results were compared to findings obtained at laparotomy or from a clinical history suggestive of fulminating liver cancer. Of 40 patients scanned after admin. of ^{131}I -rose bengal or gold ^{198} , there were 21 true positive and 12 correct negative results; the overall diagnostic error (on the basis of 2 false positives and 5 false negatives) was 17.5%. On the basis of admin. of sulfobromophthalein to 25 patients, there were 13 true positives, 3 correct negatives and diagnostic error was 36%. After 32 estimations of alkaline phosphatase, there were 16 true positives, 4 correct negatives and diagnostic error was 37.5%. After 32 estimations each of serum glutamic oxalacetic and serum glutamic pyruvic transaminases, there were, resp., 16 and 10 true positives, 9 and 9 correct negatives, and diagnostic errors were 22% and 40.6%. With the use of all tests, 92.3% of confirmed cases of metastatic carcinoma of the liver could be correctly diagnosed.

LIVER AND BILIARY TRACT

- 6812 CHRONIC BILIARY OBSTRUCTION--HEPATIC CHANGES. AN EXPERIMENTAL STUDY IN DOGS. (E.) Chandra, A. (Govt. Med. Coll., Patiala, India) and R. Dass. Indian J. Surg. 28(2):102-111, 1966.

Chronic obstruction of the bile duct was accomplished in adult mongrel dogs by wrapping the duct with cellophane. In 14 dogs only the common bile duct was subjected to this obstruction, in 4 dogs only the cystic duct was treated and in 5 dogs both ducts were involved. The biliary obstruction produced caused variable degrees of structural changes in the liver. The latter varied with the degree, duration and site of obstruction in the biliary duct system. Common bile duct obstruction when combined with cystic duct obstruction produced more severe changes in the liver than when only one of the two was subjected to obstruction. The cystic duct obstruction, when protracted, produced changes in the liver simulating those of common bile duct obstruction. Spontaneous restoration of the continuity of the common bile duct occurred in 35% of the dogs, usually 9-10 wk. after operations as a result of invagination of the affected area; in these cases the liver did not show complete recovery due to the persistence of intraluminal obstruction.

- 6813 OSTEOPOROSIS, SCURVY, AND SIDEROSIS IN JOHANNESBURG BANTU. (E.) Seftel, H. C. (U. Witwatersrand, Johannesburg, South Africa), C. Malkin, A. Schman, C. Abrahams, S. R. Lynch, R. W. Charlton and T. H. Bothwell. Brit. Med. J. 1(5488):642-646, 1966.

The clinical, radiologic, biochemical, and pathologic features of 32 Bantu subjects with severe spinal osteoporosis are described. Apart from scurvy in 14, their diet was similar to that of the general African population. All subjects, however, consumed large quantities of a local brew which was acid in reaction and which picked up iron from the metal containers in which it was usually prepared. Serum iron was significantly elevated in the osteoporotic patients compared to 41 male in-patients who were being treated for non-infective conditions. The degree of siderosis was assessed further in 16 males and 2 females by histologic study of liver biopsy specimens. Using the criteria described by Bothwell and Bradlow, 17 were found to be severely siderotic and one moderately so. In 2 subjects who came to autopsy, the liver and spleen were enlarged and of a deep rust color. The duodenum, upper part of the jejunum, and abdominal lymph nodes were similarly colored. In one case, the conc. of iron, per 100 g dry wt., was, for liver 3.4%, for spleen 5.7%.

- 6814 LIVER IRON AND DESFERRIOXAMINE-INDUCED URINARY IRON EXCRETION. (E.) Hallberg, L. (Sahlgrenska Hosp., Goteborg, Sweden), L. Hedenberg and A. Weinfeld. Scand. J. Haemat. 3(2):85-98, 1966.

In a continuation of earlier studies, the desferrioxamine-induced urinary iron excretion was measured in subjects in whom surgical biopsy specimens were used to determine liver non-hemin iron. In untreated normals, 24-hr. urinary iron excretion was an av. of 0.07 mg (0.03-0.15). In 10 females, av. urinary iron excretion after desferrioxamine was 0.46 mg; in normal males, av. excretion was 0.70 mg. The difference in mean excretion between males and females was statistically significant. In 2 males with portal cirrhosis the iron excretion was 1.36 and 1.46 mg per 24 hr. There was a very high correlation between the increase of urinary iron excretion after admin. of desferrioxamine on the one hand and the conc. of total non-hemin, ferritin, and hemosiderin iron of the liver on the other.

- 6815 III. TREATMENT OF ENDOGENOUS HEPATIC COMA WITH COENZYME A, α -LIPIC ACID, DIPHOSPHOPYRIDINE NUCLEOTIDE, AND COCARBOXYLASE. (Fr.) Thölen, H. (Saint Antoine Hosp., Paris), A. Colombi and G. Engelhart. Rev. Medicochir. Mal. Foie 41(1):19-30, 1966.

Seventeen patients in hepatic coma of various causes (8 acute or subacute hepatitis; 7 serum hepatitis; 1 purulent cholangiohepatitis; 1 mushroom poisoning) were treated

LIVER AND BILIARY TRACT

with a combination of coenzyme A, thioctic acid, diphosphopyridine nucleotide, and cocarboxylase; results were positive in 14 (82%) and negative in 3 (18%; 2 of 3 died after the first infusion). Positive results were seen in 5 of 6 patients in Stage VI, 2 of 4 in Stage III, and 7 of 7 in Stage II of coma. Results of treatment were positive in 11 of 16 patients in hepatic coma as a result of cirrhosis; of these 2 of 3 were in Stage IV, 3 of 4 were in Stage III, and 7 of 9 were in Stage II. Pyruvic acid levels were either decreased or increased as a result of treatment, while acetoin-2,3-butyleneglycol levels were decreased after treatment in nearly all patients. Results of histological examination of hepatic tissue before and after treatment are reported for some patients.

- 6816 ANGIOTENSIN RESPONSE IN VARIOUS LIVER DISEASES WITH SPECIAL REFERENCE TO LIVER FUNCTION TESTS. (E.) Bisht, D. B. (Jawaharlal Inst. Postgrad. Med. Ed. Res., Pondicherry, India), K. Uthamalingam and M. B. Pranesh. J. Assn. Physicians India 14(3):159-160, 1966.

Response to a single inj. of angiotensin II (2.5 µg dissolved in 5% glucose) was studied in 45 patients with various liver diseases. Response was classified as ++ (when both systolic and diastolic pressure showed a rise of more than 10 mm Hg), +- (when only systolic pressure rose more than 10 mm Hg), -+ (when only diastolic pressure rose more than 10 mm Hg), -- (when neither pressure rose more than 10 mm Hg), or N.R. (when subsequent fall of more than 10 mm Hg from the resting level was observed). In the authors' series, results were ++, +-, -+, --, and N.R. in 18, 3, 1, 0, and 2, resp., of 22 patients with infectious hepatitis with mild to severe liver damage but not in hepatic coma; 6, 1, 1, 0, and 0, resp., in 8 patients with amebic hepatitis with moderate to gross hepatic enlargement but no appreciable liver damage; 5, 3, 0, 0, and 0, resp., in 8 patients with amebic liver abscess with gross hepatic damage; 5, 2, 0, 0, and 0, resp., in 7 patients with severe malnutrition and anemia with mild to moderate impairment of liver function. Not a single case showed a completely negative response, which is a frequent feature of cirrhosis. Liver function was assayed by standard tests. No correlation was seen between the degree of liver damage and angiotensin response.

- 6817 CLINICAL, HISTOCHEMICAL, AND ULTRASTRUCTURAL STUDIES OF TWO CASES OF THE DUBIN-JOHNSON-ROTOR SYNDROME. (It.) Barone, P. (U. Messina, Italy), C. Infrerra and F. Tigano. Arch. Ital. Anat. Istol. Pat. 39(6):431-478, 1965.

Clinical and histological studies were performed in 2 brothers (age 32 and 24 yr.) with chronic idiopathic jaundice. Data indicates an intermediate stage between the Dubin-Johnson (with hyperpigmentation of the liver) and Rotor (without parenchymal pigmentation) syndromes. Both brothers presented with chronic, benign jaundice, increased blood levels of free and conjugated bilirubin, absence of hemolysis, delayed sulfobromophthalein elimination, lack of visualization of the gallbladder, and slight or lack of impairment of hepatic function. The pigment had staining properties similar to those of lipofuscin. Liver structure was well preserved; no inflammation or obstruction was noted; hepatocyte swelling was more intense 24 hr. after the admin. of sulfobromophthalein. Electron microscopy of liver biopsy specimens revealed the following: reduction in number and swelling of granulations; vesicular degeneration and fragmentation of the endoplasmic reticulum and Golgi apparatus; marked accumulation of both lipofuscin-like and bile-like pigment; reduction in the number of mitochondria with infrequent abnormalities; no appreciable alteration of the microvilli or capillary size.

- 6818 SULFONAMIDES COMPETING WITH BILIRUBIN FOR CONJUGATION TO ALBUMIN. (E.) Josephson, B. (Eriks Hosp., Stockholm, Sweden) and P. Furst. Scand. J. Clin. Lab. Invest. 18(1):51-63, 1966.

LIVER AND BILIARY TRACT

The binding of various sulfonamides and of bilirubin to serum protein or pure albumin was studied by means of ultrafiltration and Sephadex column separation. Sulfamethoxypyridazine and sulfamoxole (sulfadimethyloxazole) were added to sera from premature infants with jaundice and to sera from adult patients with jaundice containing only indirect bilirubin. The above 2 sulfonamides and sulfafurazole (sulfisoxazole) in the same conc. as above were added to normal sera to which bilirubin had been added in precalculated conc. (10-35 mg of bilirubin/100 ml). Upon ultrafiltration, free bilirubin appeared in the ultrafiltrate only if the bilirubin conc. was greater than 20 mg/100 ml and the conc. of the sulfa compound was approx. 25 mg/100 ml or more. Sulfonamides with a low affinity for albumin were not able to replace albumin-bound bilirubin, but sulfamethoxypyridazine, sulfamoxole, and sulfafurazole have a high protein-binding capacity and contain an oxygen atom. Sephadex column separation confirmed these findings. Results suggest that the serum conc. of sulfonamides which might produce kernicterus in premature infants is above 15 mg/100 ml even for sulfonamides with a high affinity for albumin.

Hepatic Injury

- 6902 PHENOBARBITAL-INDUCED FINE STRUCTURAL CHANGES IN RAT LIVER. (E.)
Burger, P. C. (Northwestern U. Sch. Med., Chicago, Ill.) and P. B.
Herdson. Am. J. Path. 48(5):793-810, 1966.
Liver structural changes were studied in rats after admin. for 10 days of sodium phenobarbital by various routes (p.o., 0.1% by wt. of diet; 100 mg/kg by gavage daily, 100 mg/kg i.p. daily). All rats showed liver enlargement and hepatic fine structural changes regardless of the route of admin. of the drug or incorporation into the diet. The most striking changes include proliferation of smooth endoplasmic reticulum with concomitant shortening and dispersion of rough endoplasmic cisternae, mitochondrial abnormalities, and the development of myelin figures. The morphologic abnormalities at first affect only central cells, but progressively involve cells further out in the lobule so that after medication for 10 days most of the lobule is involved. Nevertheless, a peripheral zone of normal-looking cells is always present. When the admin. of sodium phenobarbital is combined with the barbiturate potentiator SKF 525-A (β -diethylaminoethyl diphenylpropylacetate HCl), abnormalities of the same type are more extensive after treatment for several days than with phenobarbital alone. SKF 525-A itself causes no detectable abnormalities.
- 6903 ACUTE ETHANOL POISONING AND LIVER METABOLISM. (Ger.) Ammon, H. P. T.
(U. Erlangen, Germany), C.-J. Estler and F. Heim. Arch. Inst. Pharmacodyn. 159(2):258-268, 1966.
Within the first 10-30 min. after admin. of ethanol (4.1 mg/g i.v.) to mice, anaerobic carbohydrate breakdown and glycogenolysis in the liver were stimulated. In the next phase (30 min.-10 hr. after treatment), anaerobic carbohydrate breakdown was gradually repressed, as shown by an increase in glycogen, a decreased lactate/pyruvate quotient, and decreased hepatic lactate conc. After alcohol had disappeared from the blood, hepatic lactate and blood glucose were still decreased. High-energy phosphate production in the liver was also suppressed by ethanol. Coenzyme A activity fell by over 90% within the first 2 hr., then rose to control levels after 20 hr. It is suggested that coenzyme A inhibition results from the formation of a semimercaptal between coenzyme A and acetaldehyde.
- 6904 ELECTRON MICROSCOPIC AND MORPHOMETRIC STUDIES OF THE RABBIT LIVER AFTER INTRAVENOUS INJECTION OF ORGANICALLY BOUND COPPER. (Ger.) Wessel, W.
(U. Bonn, Germany), P. Gedigk and O. Giersberg. Virchow Arch. Path. Anat. 340(3):206-230, 1966.
In rabbits admin. 2-69 inj. of a copper-ethylenediaminetetraacetate complex over 1-49 wk., the hepatic parenchymal cells took up the copper in a finely dispersed form. In the Kupffer cells, however, copper was taken up in large aggregates and stored in phago-lysosomes which later developed into lysosomes. Storage and digestion took place in the preformed lysosomes, which formed in large numbers a short time after the beginning of treatment. Both the Kupffer cells and the parenchymal cells showed an accumulation of a plasma protein-like substance around the copper particles; this substance became increasingly osmiophilic during storage of the metal particles. Total mitochondrial vol. was increased through the first 40 wk. of the study; at the end of the study, the mitochondria of the severely damaged cells showed a distinct swelling but a decreased vol.
- 6905 CARBOXYL ESTERASE ACTIVITY IN THE LIVER OF DOGS AFTER INTRAVENOUS INJECTION OF SMALL DOSES OF ETHIONINE. (Pol.) Torzecki, Z. (Inst. Path. Anat. Med., Lodz, Poland). Pat. Pol. 17(1):1-7, 1966.
Hepatic carboxyl esterase activity was determined (Holt-Withers method) in 35 dogs following i.v. inj. of ethionine (18-23 mg/kg/day) for 1-21 days. A prompt and marked decrease in enzyme activity was observed in treated animals; after 5 days, no enzyme activity was detected by this method. On day 6, microscopic studies

revealed clusters of numerous liver cells with high esterase activity and 2-3 nuclei in each cell.

- 6906 THE EFFECT OF HIGH ENERGY LASER PULSES ON THE PRIMATE LIVER. (E.)
Mullins, F. (NCl, Bethesda, Md.), J. P. Minton, R. C. Hoyer, J. R. Dearman
and W. B. McKnight. Surg. Gynec. Obstet. 122(4):727-732, 1966.

Surgically accessible areas of the livers of 12 rhesus monkeys were exposed to 5-40 impacts of irradiation from a neodymium laser; the amount of energy delivered ranged from 3,436-29,350 joules. After acute exposure the incision was closed and the animals were allowed to recover; all survived the acute effects. In studies which extended to 8 wk. after exposure, gross and histologic investigation showed that the laser lesions healed rapidly without immediate or delayed hemorrhage or infection. That the healing of the thermal injury was rapid was indicated by the prompt return to normal of liver function studies. There were, however, significant increases in serum glutamic oxalacetic and pyruvic transaminases and especially in serum lactic dehydrogenase. There was mild, transient elevation in serum alkaline phosphatase. These elevations lasted about 2 wk.

- 6907 AUTOAGGRESSION IN HEPATOLOGY. EXPERIMENTAL STUDY. III. EFFECT
OF 2,3,5-TRIETHYLENIMINO-p-BENZOQUINONE ON HEPATIC LESIONS CAUSED BY
PARENTERAL ADMINISTRATION OF AUTOLOGOUS LIVER HOMOGENATE AND FREUND'S
COMPLETE ADJUVANT IN RATS. (It.) Ghetti, A. (U. Florence, Italy),
F. Pacini, F. Corradi, A. Panerai, G. Morace and A. Morettini. Riv.
Crit. Clin. Med. 65(3):350-355, 1965.

In hepatectomized Sprague-Dawley rats (av. wt. 180 g) treated s.c. with 1 ml/wk. of autologous liver homogenate in Freund's complete adjuvant for 12 wk. beginning 30 days after hepatectomy, concomitant i.p. inj. of 2.5 µg of 2,3,5-triethylene-imino-p-benzoquinone (Trenimon) twice a wk. for the same period prevented the appearance of hepatic lesions which usually occurred following the admin. of the homogenate in Freund's adjuvant. Microscopic findings in Trenimon-treated animals were practically similar to those in control animals subjected to hepatectomy alone. As a possible explanation of the mechanism of this protective action of Trenimon, the authors suggest a specific inhibitory effect on cellular immunity rather than on antibody production, as well as a general antiphlogistic effect. (See also the following abstract.)

- 6908 AUTOAGGRESSION IN HEPATOLOGY. EXPERIMENTAL STUDY. VI. EFFECT OF
SPLENECTOMY ON HEPATIC LESIONS CAUSED BY PARENTERAL ADMINISTRATION OF
AUTOLOGOUS LIVER HOMOGENATE AND FREUND'S COMPLETE ADJUVANT IN RATS.
(It.) Corradi, F. (U. Florence, Italy), F. Pacini, A. Ghetti, A.
Panerai, G. Morace and A. Morettini. Riv. Crit. Clin. Med. 65(4):474-
486, 1965.

Histological examination of the liver was performed in partially hepatectomized female Sprague-Dawley rats (wt. 150 g) subjected to splenectomy 10 days before (Group I) or 5 wk. after (Group II) s.c. inj. of 0.5 ml of autologous liver homogenate in 0.5 ml of Freund's adjuvant once a wk. for 5-10 wk. In Group I, mortality was 30% (3 of 10 rats); histological findings revealed moderate cellular infiltration at the level of the portal spaces and blood vessels, signs of vacuolar degeneration of hepatocytes, and rare necrotic foci; these changes were similar to those observed in controls treated by autologous liver homogenates and Freund's adjuvant alone. After 5 wk. of treatment, animals of Group II showed a mortality of 50% (5 of 10 rats); the 5 surviving rats developed laminar distortion, foci of necrosis frequently localized in the centrilobular area, and diffuse parvicellular infiltration with tendency toward the formation of aggregates around the portal spaces. Results indicate that splenectomy enhances the hepatotoxic effects of inj. of autologous liver homogenates and Freund's adjuvant observed in the authors' previous experiments, most likely because of the important role of the spleen in antibody formation in the organism. (See also the preceding abstract.)

- 6909 CHANGES IN THE HISTOCHEMICAL PICTURE OF LIVER LIPIDS IN RATS TREATED WITH NICOTINAMIDE. (It.) Fruschelli, C. (U. Siena, Italy) and G. Pompucci. Boll. Soc. Ital. Biol. Sper. 41(23):1440-1443, 1965.
Hepatic lipid content was studied in female Wistar rats (wt. 200 g) given a single i.p. inj. of nicotinamide (100 mg/100 g body wt.) and kept on a liquid diet until sacrifice; controls were fed only a balanced diet ad libitum. In controls, large numbers of fat droplets were aggregated in the hepatocytes of the peripheral portion of the lobule, i.e., around the periportal spaces; the droplets decreased in number in hepatocytes closer to the centrolobular vein. In nicotinamide-treated rats, fat accumulation took place in 2 phases: (1) progressive decrease in the number of fat droplets (same periportal localization as controls) up to 12 hr. after treatment, at which time practically no droplets were visible; (2) progressive increase in the number of fat droplets up to abnormal levels, but with no cellular or nuclear alterations, was observed from hr. 16 on. Phase I is considered to be due either to a primary effect on hepatic fat content in which "metabolic lipids" are converted into "structural lipids", or to a reduction in the amount of "metabolic lipids". Phase II is thought to be due either to enzymatic alteration of the cellular mechanism as a result of massive doses of nicotinamide, or to extra-hepatic influences acting directly on the hepatocyte.
- 6910 DIFFERENTIAL EFFECTS OF A STRESS ON LIVER ENZYMES IN ADULT AND INFANT RATS. (E.) Schapiro, S. (VA Hosp., San Fernando, Cal.), E. Geller and A. Yuwiler. Neuroendocrinology (Basel) 1(3):138-143, 1965-1966.
Adult and infant Sprague-Dawley rats were subjected to stress by placing them on a noisy, reciprocating shaker for 30 min. About 3.5-4 hr. later the rats were sacrificed and transaminases were determined in the supernatant fraction of liver homogenate. Four- and 8-day old rats responded to stress by large increases in tyrosine and tryptophan transaminases. The adult rats exposed to this same stress did not exhibit this change. In the adult rat the inducing effects of cortisol on transaminase activities are blocked by this stress. These results suggest the activation of a mechanism(s) in the adult rat which opposes the enzyme-inducing effects of cortisol. This mechanism is non-functional during early postnatal life. When infant and adult rats were given 3 mg and 5 mg/100 g, resp., of cortisol succinate, plasma corticosteroid level after 4 hr. was 51.4 and 16.2 μ g/100 ml, resp.
- 6911 VARIOUS EFFECTS OF TRITON ON RATS INTOXICATED WITH CARBON TETRACHLORIDE. (It.) Ajello, M. T. (Superior Inst. Health, Rome), R. Angelico, G. Cavina, M. Manganaro and L. Moretta. Boll. Soc. Ital. Biol. Sper. 42(3):104-106, 1966.
Hepatic lipid content was studied in Wistar rats (av. wt. 200 g) treated with carbon tetrachloride (CCl_4 ; 0.05-0.25 ml/100), Triton (WR 1339; 50 mg/100 g), or a combination of both. Increased hepatic triglyceride (up to 13.13 mg/g organ wt. as compared to 7.53 mg/g in untreated controls) and diglyceride levels, but decreased serum triglyceride levels, were observed in CCl_4 -treated rats; Triton increased serum triglyceride levels 6-7-fold as compared to controls, but the increase was only 2-3-fold when CCl_4 was also admin.; Triton had no effect on hepatic lipid content but significantly increased serum levels of phospholipids and diglycerides along with triglycerides. Total serum cholesterol levels were not affected by Triton, although the ratio of free/esterified cholesterol was shifted toward the former; rats treated with both CCl_4 and Triton showed a decrease in total serum cholesterol and the same shift in the free/esterified cholesterol ratio. Inhibition of the effect of Triton on serum lipids by CCl_4 seems to confirm the hypothesis that the liver is the main source of serum triglycerides.
- 6912 LYMPHATIC CIRCULATION OF THE LIVER IN EXPERIMENTAL POST-HEPATIC VENOUS STENOSIS. (Fr.) Mallet-Guy, P. (U. Lyon Fac. Med., France), J. Michoulier,

C. Pera Madrazo, A. Pissidis and J. Leroy. Bull. Soc. Int. Chir. 25(1): 68-75, 1966.

The passage of bile from the bile ducts to the lymphatic system was studied in dogs subjected to incomplete ligation of the inferior vena cava below the entry of the sub-hepatic veins. Abundant formation of ascites was constantly observed after 1-25 days. Significant increase in bile duct pressure (37 cm H₂O as compared to 31.6 in normal animals) was necessary before passage of Chicago blue from the duct into the lymphatic system. Electronic manometric studies of lymph pressure in pre- and post-ganglionic lymph nodes showed no significant difference in normal or experimental animals. In an attempt to evaluate the efficacy of thoracic drainage in the treatment of ascites in patients with cirrhosis, no change in pressure was observed in the lymph nodes immediately draining the liver in dogs subjected to thoracic duct drainage. Results indicate that these lymph nodes act as a barrier between thoracic duct and the lymphatic vessels draining the liver.

- 6913 LYMPHATIC CIRCULATION OF THE LIVER IN EXPERIMENTAL TOXIC HEPATITIS. (Fr.) Mallet-Guy, P. (U. Lyon Fac. Med., France), J. Michoulier, J. Feroldi, M. Nugeyre and P. L. Castelfranchi. Bull. Soc. Int. Chir. 25(1):76-82, 1966.

The passage of bile from the bile ducts to the lymphatic system was studied in 15 dogs (wt. 7-19 kg) in which hepatitis was induced by i.p. inj. of 500 mg/kg of carbon tetrachloride followed 1-4 days later by a second inj. Passage was demonstrated by the appearance of Chicago blue in the lymph after inj. into the common bile duct. In animals with induced hepatitis, the dye passed into the lymphatic system only after the pressure in the duct reached an av. of 40.8 cm H₂O as compared to 31.6 cm H₂O in normal dogs. Upon passage of the dye into the lymphatic system, the pressure dropped to 20% of the normal. As evidenced by determination of serum glutamic pyruvic transaminase, correlation was observed between the intensity of hepatic lesions and the increase in pressure. In similar experiments with barium suspension, passage from the common bile duct into the lymphatic system failed to occur at usual experimental doses. Results indicate the existence of lymphatic stasis in the course of hepatitis.

- 6914 COMPLICATIONS FOLLOWING THE USE OF A PLASMA EXPANDER, ESPECIALLY POLY-VINYLPYRROLIDONE SOLUTION. (E.) Honda, K., R. Motoki, H. Sakuma and M. Watanabe. Int. Surg. 45(5)(Pt. 1):539-547, 1966.

In a group of 144 cases (59 chest diseases, 73 abdominal diseases, 12 other diseases) in which 3.5% middle molecular polyvinylpyrrolidone soln. was used as a plasma expander, 49 developed complications which increased with the amount of expander used. At autopsy, storage in the liver was noted in 16 cases. Seven had no known hepatic disease, 6 had shown transient jaundice, and 6 had jaundice of long duration. In the latter group, 5 of the 6 patients had received large doses of expander (over 100 g); in contrast, only 3 of 9 patients with transient jaundice received this much. Complications involving the intestine were found in 16 cases. In 4 cases the complications were serious (hematemesis and melena seen to a marked degree or on consecutive days). In 3 of these cases over 140 g of expander had been admin.

- 6915 HISTOCHEMICAL INVESTIGATIONS OF THE LIVER IN CARBON TETRACHLORIDE POISONING. (E.) Cotutiu, C. (Medico Legal Inst., Bucharest, Rumania) and D. Streja. Acta Histochem. (Jena) 23(1-4):1-8, 1966.

A histochemical study was made of the livers of rats 2, 4, 6, 12 and 24 hr. after admin. of CCl₄ (1.5 ml of a 10% soln., i.m.). The accumulation of lipids in the liver was correlated with changes in the activities of some enzymes. The first change observed was the disappearance of glucose-6-phosphatase in the central area. Later, with the accumulation of unsaturated fats, there was loss of the activities of succinic dehydrogenase, monamine oxidase, and adenosinetriphosphatase. Non-specific esterase and acid phosphatase activities may sometimes be increased. The histologic lesions in the liver became pronounced after 9-12 hr.

- 6916 ANTIBODIES AGAINST THE MITOCHONDRIAL FRACTION OF LIVER AFTER TOXIC LIVER DAMAGE IN RATS. (E.) Pinckard, R. N. (U. Edinburgh Sch. Med., Scotland) and D. M. Weir. Clin. Exp. Immunol. 1(1):33-43, 1966.

The complement-fixing liver antigen that reacted with rat serum containing the carbon tetrachloride-induced "IgM" antibody was associated primarily with the mitochondrial fraction of the liver cells; a somewhat smaller fraction was found in the nuclear fraction. The antigen was very labile to freeze-thawing, extraction, and heat; it was not possible to isolate a specific protein, lipoprotein, or lipopolysaccharide moiety. The presence of lysosomes that would autolyze the antigenic components was believed to account for the lability of this antigen. It is concluded that the particulate nature of this antigen explains both the presence of antibody activity in the IgM serum fraction and the inability to induce tolerance to the antigen. The host may be unable to develop tolerance to particulate subcellular components.

- 6917 CHROMOCENTERS IN THE LIVER CELLS OF THE MOUSE UNDER NORMAL AND PATHOLOGICAL CONDITIONS. (Ger.) Muller, H.-A. (U. Würzburg, Germany). Ergebn. Allg. Path. 47:144-185, 1966.

The liver cells of mice treated with the non-carcinogen thioacetamide showed an increase in nucleolar size, with a marked reduction in the number of "chromocenters" (chromatin-containing material in the interphase nucleus), which indicated a reduction in the number of chromosomes to the diploid state. In untreated rats, most of the liver cells were tetraploid; autoradiographic studies indicated a parallel between the number of chromocenters, the DNA conc., and ploidy. In thioacetamide-treated liver, the nuclei appeared "clear" at first; later, fine granules began to form, and after prolonged treatment the granules tended to form chain-like structures. After admin. of the carcinogen N-nitrosomorpholine, most of the cells showed finely granulated, very large nuclei, with the number of chromocenters and the DNA conc. corresponding to octaploid and even higher chromosome numbers. This compound acted as a pre-prophase inhibitor; thioacetamide did not act on the cells during interphase III, since the prophase pattern developed in these cells. A literature review (217 references) on the functional and metabolic significance of the chromocenters is included.

- 6918 ELECTRONMICROSCOPIC AUTORADIOGRAPHY OF ³H-GLYCEROL LABELED LIPID IN ETHANOL INDUCED FATTY LIVER. (E.) Stein, O. (Hadassah Med. Sch., Jerusalem, Israel) and Y. Stein. Exp. Cell Res. 42(1):198-201, 1966.

Glycerol esterification and intracellular lipid transport were studied in female rats (wt. 70-80 g) fasted for 16 hr. and then given ethanol (0.6 g/100 g body wt.) by stomach tube, followed 4 hr. later by i.v. inj. of 2-³H-glycerol (5 mc) in saline. Rats were sacrificed 5 and 10 min. after inj. and radioactivity uptake was determined in various organs. The liver was the major site of glycerol uptake and esterification; approx. 90% of the esterified lipids were recovered as neutral glycerides. Electron microscopy of liver fragments revealed a well preserved hepatic architecture but for the accumulation of lipid droplets ranging from 200-700 m μ in diameter. Five min. after inj., autoradiographic grains were localized in the vicinity of the sinusoidal border and over lipid droplets, and the labelled product was found in regions of the endoplasmic reticulum but not in larger lipid droplets. At 10 min. after inj., the label was still present over elements of the endoplasmic reticulum but was conc. over lipid droplets 250-700 m μ in diameter. Results suggest that the autoradiographic reaction is due to the presence of labelled esterified lipids formed in situ from labelled α -glycerophosphate.

- 6919 EFFECT OF ACUTE ETHANOL INTOXICATION ON PORPHYRIN METABOLISM AND HEPATIC ATP, DIPHOSPHOPYRIDINE NUCLEOTIDE, REDUCED DIPHOSPHOPYRIDINE NUCLEOTIDE,

AND LIPID LEVELS IN WHITE RATS. (Fr.) Gajdos, A. (Charity Hosp., Paris), M. Gajdos-Török, A. Palma-Carlos and L. Palma-Carlos. C. R. Soc. Biol. (Paris) 159(11):2185-2188, 1965.

Liver metabolism was studied in the liver of white rats treated with ethanol at various doses and for varying periods. In rats treated with i.p. inj. of 15 ml/kg of a 33% ethanol soln. twice daily for 2 days, hepatic levels of ATP were decreased while those of porphyrin, lipids, and oxidized or reduced diphosphopyridine nucleotide (with no change in the ratio of the latter 2) were increased; urinary and fecal porphyrin was unchanged. In rats treated with 50% of the above dose for the same length of time, hepatic and RBC levels of porphyrin were increased, hepatic ATP was decreased, and hepatic levels of oxidized and reduced diphosphopyridine nucleotide were unchanged; urine and fecal porphyrin levels were practically normal. In rats treated with i.p. inj. of 7.5 ml/kg of a 33% ethanol soln. twice daily for 8 days, hepatic and RBC levels of porphyrin were markedly increased, hepatic levels of ATP were lowered, hepatic lipid content was increased, and hepatic levels of reduced diphosphopyridine nucleotide were more markedly increased than those of the oxidized form; urinary and fecal porphyrins were practically normal. Results indicate a stimulating effect of ethanol on porphyrin metabolism accompanied by a decrease in hepatic ATP as was observed by the authors in previous studies with 6-mercaptapurine, orotic acid, and ethionine.

6920 DEGENERATION AND EOSINOPHILIC NECROSIS OF LIVER CELLS IN EXPERIMENTAL MATERIAL. (Pol.) Zyss, R. Pat. Pol. 17(1):61-66, 1966.

Microscopic and histochemical studies of the liver were carried out in acute poisoning with carbon tetrachloride (6 rabbits), in acute diffuse inflammation of the peritoneum (20 rats), and in acute radiation sickness (10 rats) as well as in liver biopsy specimens from 6 cases of infectious hepatitis and from 10 cases of cholelithiasis. The eosinophilic degeneration of hepatic cells consisted of eosinophilic bodies and inclusions which behaved like denatured, insoluble protein, possibly albumin. It is concluded that biochemical injury is followed in a few hours by the appearance of these eosinophilic inclusions. The eosinophilic degeneration is reversible during its early stages. Kupffer cells are phagocytic towards these eosinophilic bodies.

6921 HEPATIC BIOPSY FINDINGS DURING THE COURSE OF SENECIOSIS INDUCED EXPERIMENTALLY IN HORSES BY FEEDING WITH GROUNDSEL (Senecio erraticus barbaeifolius). (Cz.) Vaňek, J. (LFKU, Pilsen, Czech.), Z. Sova and J. Jícha. Sborn. Ved. Prac. Lek. Fak. Karlov. Univ. 8(4):449-456, 1965.

Seneciosis in man and animals has been reported in South Africa, Jamaica and the Central Asian Republics of USSR. Repeated liver biopsies were carried out in 4 horses fed small doses of dried groundsel for long periods. Dry groundsel was added to hay and given 1-2 x/day; powdered leaves and blossoms of Senecio were mixed with oats. Horse I (male; 4 yr. old) received a total dose of 97 kg over 10 mo. with intervals of 11 days; the animal started to lose wt. within 1.5 mo., developed severe jaundice, apathy, and died in coma. Horse II (male; 4 yr. old) received a total dose of 102 kg over 12 mo.; no marked changes occurred during the first 9 mo., then the animal developed jaundice, apathy, concomitant infection, hepatic coma, and was sacrificed. Horse III (female; 9 yr. old) received a total of 55 kg over 6 mo.; concurrent infections developed and were treated; no jaundice was observed. Horse IV (female; 7 yr. old) received a total dose of 207 kg over 4 yr.; no symptoms were noted during the first yr., but jaundice developed after 15 mo. and lasted 11 mo. after suspension of the groundsel. Biopsy findings showed a variable latent period which depended on the size of the dose. The first stage of hepatic changes consisted of diffuse enlargement of liver cells with some necrotic alterations, resorption granulomas, and increased frequency of binuclear cells and enlarged nuclei. During the second stage, in addition to cellular changes,

LIVER AND BILIARY TRACT

Hepatic Injury

enlargement or fusing of the portal vessels (which become less distinctly demarcated), moderate inflammatory infiltration, focal interlobular fibrosis, and thickening of the walls of the central and sublobar veins were observed. Changes in hepatic veins are a secondary result of the hepatotoxicity of Senecio and not primary as in Chiari's syndrome.

- 6922 EFFECT OF DENERVATION OF THE COMMON HEPATIC ARTERY ON INFLAMMATION IN THE LIVER. (Pol.) Oleszkiewicz, L. (Clin. Surg., Acad. Med., Wroclaw, Poland). Pat. Pol. 17(1):99-106, 1966.

Twenty-six male and female dogs (wt. 10-37 kg) were fasted for 24 hr. and subjected to various surgical procedures: Group 1 (9 dogs) underwent laparotomy, liver biopsy, and neurectomy of about 2 cm around the common hepatic artery (= Subgroup A₁) with laparotomy and biopsy repeated 7 days later (= Subgroup B₁); Group 2 (9 dogs) received a single i.p. inj. of carbon tetrachloride (0.5 ml/kg) to induce hepatitis with laparotomy, liver biopsy, and neurectomy carried out 7 days (= Subgroup A₂) and 14 days (= Subgroup B₂) after the inj.; Group 3 (8 dogs) were treated similarly but neurectomy was not carried out, and liver biopsy was performed 7 days (= Subgroup A₃) and 14 days (= Subgroup B₃) after carbon tetrachloride inj. The utilization of O₂ (microliters/mg of dry liver tissue) after 60 min. of respiration as determined by the Warburg apparatus was 3.18 in A₁; 2.63 in B₁; 4.28 in A₂; 3.58 in B₂; 4.25 in A₃; 4.29 in B₃. It is concluded that: 1) denervation of the common hepatic artery in both normal and inflamed liver results in a decreased utilization of O₂ by liver tissue; 2) inflamed liver tissue utilizes more O₂ than normal liver tissue; 3) the increased O₂ utilization by inflamed liver tissue is about the same after 14 days as after 7 days. Histological studies showed inflammation in A₂ and A₃ (17 dogs), necrosis in 8 of 17, and fatty degeneration in 10 of 17. In Subgroup A₂, fatty degeneration was found in 5 of 9 dogs, but disappeared 7 days after neurectomy. In Group 3, fatty degeneration was found after 7 days in 5 of 8 animals of Subgroup A₃ and after 14 days in Subgroup B₃. A marked increase in hepatic glycogen was seen in neurectomized animals (Subgroups B₁ and B₂) with respect to Subgroup A₁ and A₂. No differences in hepatic glycogen levels were seen in Subgroups A₃ and B₃.

- 6923 VARIATIONS IN PHOSPHOLIPID AND NUCLEIC ACID CONTENT OF THE LIVER OF RATS SUBJECTED TO CARBON TETRACHLORIDE INTOXICATION. (It.) Comunale, A. (Nat. Inst. Biochem., Rome). Gazz. Int. Med. Chir. 71(2):168-173, 1966.

Hepatic phospholipid and nucleic acid content was determined in albino rats (wt. 130-160 g) fed normal diets without (Group A) or with i.m. inj. of 2 ml/kg of carbon tetrachloride (Group B). Significant reduction in hepatic levels of both phospholipids and nucleic acid were observed in rats of Group B (10.5-11.9 and 9.1-10.7 mg/g of fresh organ, resp.) as compared to rats of Group A (14.3-16.6 and 13.9-14.7 mg/g of fresh organ, resp.). A decrease in phosphorylating enzyme activity of hepatic cells is suggested as an explanation of results.

- 6924 OCTANOIC OXIDASE ACTIVITY IN RAT LIVER FOLLOWING LONG TERM ALCOHOL INTOXICATION. (Fr.) De Saint Blanquat, G. (U. Toulouse Sch. Sci., France) and R. Derache. C. R. Soc. Biol. (Paris) 159(10):2060-2063, 1965.

After feeding male Wistar rats a red wine of 10% alcoholic content (type of wine not specified) for 5 mo., histological examination of the liver revealed no lipid infiltration or other alterations. Hepatic octanoic dehydrogenase activity was increased, while levels of succinic dehydrogenase and α -ketoglutaric dehydrogenase were markedly diminished. No changes were observed in the oxidation rate of citrate, malate, glutamate or α -ketobutyrate.

- 6925 SUBACUTE CARBON TETRACHLORIDE INTOXICATION IN RATS. COMPARISON OF MICROSCOPIC APPEARANCE OF THE LIVER AND BLOOD AMMONIA LEVELS. (Fr.) Duchêne-Marullaz, P. (Sch. Med. Pharm., Clermont-Ferrand, France), B. de Laguillaumie, J. Talvard and M. Constantin. C. R. Soc. Biol. (Paris) 159(10):1977-1979, 1965.

Histological examination of liver specimens and blood ammonia determinations were conducted in Wistar rats following treatment for 1-18 days with carbon tetrachloride (0.125 ml/kg/day in olive oil). Controls were treated for similar periods of time with olive oil alone. Results indicate that not all animals with important hepatic lesions had abnormal blood ammonia levels. On the contrary, increased blood ammonia levels were always indicative of hepatic regeneration. The latter finding may be explained by the existence of arteriovenous shunts or by augmented protein needs of the organism in the course of hepatic regeneration.

- 6926 INFLUENCES OF DIETARY FAT ON ALCOHOLIC FATTY LIVER. (E.) Jones, D. P. (Harvard Med. Sch., Boston, Mass.) and E. A. Greene. Am. J. Clin. Nutr. 18(5):350-357, 1966.

In groups of male albino rats fed high fat (43%) or low fat (5%) diets plus ethanol or sucrose plus coconut oil or safflower oil, fatty livers developed only in rats fed high fat diets with ethanol whether they received coconut oil or safflower oil. The mean liver fat content was significantly higher in these animals (117 and 107 mg fat/g of wet liver) than in rats fed the other diets (38.1-51.3 mg fat/g of wet liver), in which values were within normal range and showed no significant differences from each other. Total liver wt. was greater in animals with fatty livers (statistically significant among animals fed coconut oil and ethanol) than in animals with normal hepatic lipid content. Histological examination of the liver revealed uniform distribution of fat in animals fed high fat diets and normal appearance in animals fed other diets. In a series of animals fed 10 or 20% coconut oil, mean liver fat content was within normal limits; in animals fed 20% coconut oil and ethanol, mean liver fat content approached values significantly higher than those of sucrose-fed controls, but none of the differences between the means was significant. In animals fed low fat diets, the composition of liver triglycerides was similar (predominance of palmitic and oleic acids) regardless of the type of fat or the presence or absence of alcohol in the diet. In contrast, in animals fed high fat diets, the fatty acid composition of liver triglycerides reflected that of the diet, whether they received alcohol or not and whether their liver fat content was normal or increased. In a 65-year-old male volunteer, twice as much hepatic fat accumulated when he was fed alcohol and a high fat diet than when he was fed alcohol and a low fat diet. Results indicate that the excess hepatic fat resulting from high fat diets and alcohol in rats and man is probably derived from the diet to a significant extent.

- 6927 SERUM ENZYME VARIATIONS IN ANIMALS SUBJECTED TO EXPERIMENTAL VISCERAL TRAUMA. (It.) Monsacchi, G. F. (Civil Hosp., Venice, Italy) and G. S. Ferracin. Chir. Ital. 17(1):173-183, 1965.

Serum enzyme levels were determined in rabbits following experimental induction in the liver, spleen, or kidney of traumatic lesions ranging from contusion to rupture. In rabbits with hepatic trauma, serum glutamic-pyruvic transaminase levels were increased 10-fold after 1 hr. and 20-fold after 3 hr. (in some cases), with gradual decrease (except in severe cases) after 12 hr.; serum glutamic oxalacetic transaminase levels were increased 5-fold up to hr. 12, at which time gradual decrease was observed; a reduction in the ratio of the 2 transaminases was observed; serum levels of alkaline phosphatase, aldolase, and lactic dehydrogenase showed a gradual increase, reaching abnormal values by hr. 48. Serum aldolase reached pathological levels within 3 hr. while alkaline phosphatase reached pathological levels by hr. 12 in rabbits with splenic trauma. Abnormal levels of aldolase were observed by hr. 3 in rabbits with severe renal trauma. Similar serum enzyme variations were seen in 3 patients following hepatic resection and 2 patients subjected to surgery for traumatic rupture of the liver.

- 6928 OBSERVATIONS ON TWO CHILDREN FED FLOUR CONTAMINATED WITH Aspergillus flavus FOR PROLONGED PERIODS. (Fr.) Payet, M. (U. Dakar Fac. Med. Pharm.,

Senegal), J. Cros, C. Quenum, M. Sankale and M. Moulanier. Presse Med. 74(13):649-651, 1966.

Aflatoxin, a product of the mold Aspergillus flavus, is known to induce hepatoma in the rat and hepatic damage in many other domestic and experimental animals. In 2 African children fed peanut meal containing aflatoxin for 1 yr. after reaching the age of 10 mo., clinical, biological, and histological studies 4 and 6 yr. later failed to reveal the development of malignant hepatoma. One child developed hepatic fibrosis of undetermined origin.

- 6929 ULTRASTRUCTURAL MODIFICATIONS INDUCED BY RIFAMYCIN IN MITOCHONDRIA OF RAT HEPATOCYTES. (It.) Furnò, O. (U. Messina, Italy). Boll. Soc. Ital. Biol. Sper. 41(23):1383-1385, 1965.

Ultrastructural studies were performed on rat hepatocytes following treatment with rifamycin (5 or 25 mg/kg s.c. twice daily) for 10 days. In untreated controls, normal mitochondria were round or elongated and lined with a double osmiophilic membrane whose inner layer invaginated into the uniformly granular matrix to form rare cristae. In treated animals, some mitochondria were swollen and ball-shaped (approx. 3 microns in diameter) or irregularly increased in their vol., but without rarefaction of the matrix; cristae were even more infrequent; the double membrane retained its characteristic appearance. Other mitochondria were horseshoe-shaped and had projections; cristae were reduced in number and, at times, fusiform or sacciform. In some cases, the double lining of the mitochondria was fused together for long portions, cristae were absent or very rare, and the matrix was filamentous in appearance. Results indicate that the cellular alterations induced by rifamycin concern the mitochondria (double membrane, cristae, and matrix) and not the nucleus or cell membrane. No differences were noted with the different doses admin.

- 6930 REVERSIBILITY OF HEPATIC FIBROSIS INDUCED BY CARBON TETRACHLORIDE IN THE RAT. (E.) Varga, F. (U. Pecs Sch. Med., Hungary), G. Méhes and Z. Molnár. Acta Physiol. Acad. Sci. Hung. 29(1):69-74, 1966.

The conc. of hydroxyproline in the liver of albino rats treated with CCl₄ (1 mg/kg twice weekly, s.c.) for 6, 12, 18 and 24 wk. rose 1.5, 2.3, 3.5, and 4.0-fold, resp., of the control value (255 µg/g). Hydroxyproline conc. returned to normal after 3 wk. in rats treated for 6 wk., but was still high 3 mo. after the last inj. in rats treated for more than 6 wk. Although in the 12, 18 and 24-wk. groups liver hydroxyproline conc. diminished 30-40% in 1-3 wk. after the last inj., the decrease stopped thereafter and the level remained unchanged for 1 or 2 mo. Treatment with cortisol (10 mg/kg 3 times weekly) did not enhance resorption of collagen. Liver function tests (sulfobromophthalein, total lipid, coenzyme A, calcium content) returned to normal 2-3 wk. after termination of treatment, irrespective of its duration. No parallelism was observed between the reversibility of fibrosis and the regeneration of the hepatic parenchyma.

- 6931 BIOCHEMICAL CHANGES IN THE ENDOPLASMIC RETICULUM IN LIVER INJURY. (E.) Clifford, J. (U. Coll. Hosp. Sch. Med., London) and K. R. Rees. J. Path. Bact. 91(1):215-222, 1966.

Within as early as 1 hr. after admin. of aflatoxin B₁, dimethylnitrosamine, thioacetamide, or carbon tetrachloride (CCl₄) to rats, the supernatants of liver homogenates showed a reduction in the metabolism of chlorpromazine and hexobarbitone. Admin. of ethionine did not interfere with drug detoxification. In similarly poisoned rats sacrificed after 5 hr., assay of liver fractions for glucose-6-phosphatase activity, showed a significant fall only after treatment with CCl₄ in the microsomal fraction. In additional studies, this fall could be detected as early as 1 hr. after treatment. There were no changes in distribution of protein in the liver fractions. Dimethylnitrosamine and CCl₄ treatment led to no significant change in the microsomal level of RNA, but increases were detected in the cell sap. The source of this RNA appeared to be the 9,000 g residue, which consisted of mitochondria, nuclei and cellular debris.

- 6932 FREE NUCLEOTIDES OF THE LIVER IN NORMAL RATS AND RATS INTOXICATED WITH CARBON TETRACHLORIDE. (Fr.) Cartier, P. (U. Paris Fac. Med., Sorbonne) and J. P. Leroux. Rev. Franc. Etud. Clin. Biol. 11(2):169-175, 1966.
Male Wistar rats (wt. 150-200 g) received approx. 8 g/100 g of CCl_4 by stomach tube followed by i.v. inj. 15 hr. later of 1 ml of a soln. of $\text{P}^{32}\text{O}_4\text{HNa}_2$ (radioactivity = 200 μc). A decrease in total phosphorus and nitrogen content of the liver was observed. A decrease in total free nucleotide levels of the liver, equally distributed over the pyrimidine, purine, and pyridine fractions, was also seen. Simultaneous decrease in P^{32} uptake by the nucleotides also occurred. This deficiency of nucleotide phosphorylation was probably responsible for the decreased content of its derivatives. One explanation for this seems to be an alteration of the respiratory function of liver mitochondria.
- 6933 HEPATIC TOXICITY OF TETRACYCLINE IN PREGNANCY. (E.) Allen, E. S. (U. Arkansas Sch. Med., Little Rock) and W. E. Brown. Am. J. Obstet. Gynec. 95(1):12-18, 1966.
Two groups of 9 uncomplicated gravid women, in varying stages of pregnancy, were subjected to a liver biopsy and complete liver profile including alkaline phosphatase, bilirubin cephalin flocculation, serum glutamic oxalacetic transaminase, total bilirubin thymol turbidity, and total serum protein determination. One group then received tetracycline i.v., the other oxytetracycline i.v. In both cases various individual members received 5, 10, or 15 mg/kg for 3 days; max. total daily dose was set at 2 g. When the same studies were repeated after treatment, oil red O staining of sections showed an increase of fat after treatment. All of the post-treatment liver chemistries were within normal limits, with the exception of one subject treated with tetracycline who showed an elevated transaminase value.

- 6965 LIVER RESPONSE TESTS. I. EXPLORATORY STUDIES ON GLUCOSE 6-PHOSPHATASE AND OTHER LIVER ENZYMES. (E.) Feuer, G. (Brit. Industr. Biol. Res. Assn., Carshalton, Surrey, England), L. Golberg and J. R. Le Pelley. Food Cosmet. Toxicol. 3(2):235-249, 1965.

The effect of various hepatotoxic compounds (carbon tetrachloride, safrole, allyl alcohol, coumarin, β -thujone, ethionine, thioacetamide, 3-methyl-4'-dimethylamino-azobenzene, dimethylnitrosamine, aflatoxin), food additives (butylated hydroxyanisole, butylated hydroxytoluene, sucroglyceride), stabilizers (dioctyltin, 2-phenylindole), drugs (Drazine, sodium barbitone), and other compounds (dimethylsulfoxide, Triton X-100) on liver enzyme activity was studied in rats. Significant decreases in glucose-6-phosphatase activity were observed with all hepatotoxic compounds following admin. at appropriate dose levels and for appropriate lengths of time. 2-Phenylindole and butylated hydroxytoluene in high doses also caused a decrease in glucose-6-phosphate levels, but other compounds had no effect. Glucose-6-phosphate dehydrogenase activity was increased following the admin. of carbon tetrachloride, coumarin, ethionine, dimethylnitrosamine, 2-phenylindole, and high doses

of butylated hydroxytoluene. Changes in the activity of lysosomal enzymes were not parallel; hepatotoxic compounds caused an increase in acid phosphatase and arylsulfatase but no change in β -glucuronidase and cathepsin levels; sodium barbitalone had no effect on lysosomal enzymes. No changes in mitochondrial succinic dehydrogenase activity were observed with the various compounds. (See also the following abstract.)

- 6966 LIVER RESPONSE TESTS. II. EFFECT OF COUMARIN ON GLUCOSE 6-PHOSPHATE METABOLISM IN RAT LIVER. (E.) Feuer, G. (Brit. Industr. Biol. Res. Assn., Carshalton, Surrey, England), L. Golberg and J. R. Le Pelley. Food Cosmet. Toxicol. 3(2):251-262, 1965.

A significant decrease in hepatic glucose-6-phosphatase and increase in glucose-6-dehydrogenase levels were seen after p.o. intubation with coumarin (10-20 mg/kg/day in olive oil suspension for 7 days) to albino rats. With doses of 100-200 mg/kg, marked changes in the activity of these enzymes were apparent after 2-3 days of treatment. Liver acid phosphatase activity was significantly increased only at these higher doses. Comparative studies of various characteristics of hepatic glucose-6-phosphatase in untreated and coumarin-treated rats indicated that the enzyme was located in the microsomal fraction, had the same pH optima, and was bound to isolated microsomes in the same way in both groups. Treatment with coumarin altered the kinetic parameters of glucose-6-phosphatase; hydrolysis rates in liver microsomes of glucose-6-phosphate at different conc. and the apparent Michaelis constant (K_3) and max. velocity (V_{max}) of liver glucose-6-phosphatase were reduced in treated rats. (See also the preceding abstract.)

Viral Hepatitis

- 6967 THE EFFECT OF GAMMA-GLOBULIN PROPHYLAXIS IN EPIDEMIC HEPATITIS AND IN OTHER INFECTIOUS DISEASES. (Rus.) Zibitsker, D. E. Zhur. Mikrobiol. 43(1):57-61, 1966.

After the vaccination of 25,604 preschool children with 2 inj. of γ -globulin (each 1 ml, spaced 3-6 mo. apart) a two-fold decrease was noted in the number who developed infectious diseases. After 12-20 mo., a 4.7-5.7-fold reduction was noted for epidemic hepatitis and a 2.8-5-fold reduction was seen in gastroenterocolitis. Among other infectious diseases, a reduction was also noted in parotitis and dysentery. The most pronounced decrease in infectious hepatitis was observed from days 40-90 after vaccination. The effectiveness of the vaccination showed no seasonal dependence.

- 6968 THE RESULTS OF EXPERIMENTS ON MORE RATIONAL USE OF GAMMA-GLOBULIN IN THE PREVENTION OF INFECTIOUS HEPATITIS. (Rus.) Spotarenko, S. S. and E. A. Paktoris. Zhur. Mikrobiol. 43(1):52-56, 1966.

In May of 1962, a group of 27,619 children received 1.5 or 3.0 ml of γ -globulin. During a period of 1 yr., the incidence of hepatitis (per 10,000) was 14.7 among vaccinated children; the incidence among non-vaccinated children was 28.3. The incidence among 27,566 children given the γ -globulin as part of a mass vaccination campaign was 49.7; incidence among 22,609 who were vaccinated because of the imminence of an epidemic was 96.4. During this same period, the incidence among non-inoculated controls was 144.5. On the basis of mass epidemiologic trials it is concluded that the prophylactic effect of γ -globulin with respect to infectious hepatitis is retained for 4-9 mo. There appeared to be no difference in the efficacy in the high or low dose in children aged 3-10 yr.; however, generally more γ -globulin was needed in the period before an epidemic to prevent infection.

- 6969 DYNAMICS OF CERTAIN ALLERGIC INDICES DURING TREATMENT FOR EPIDEMIC HEPATITIS. (Rus.) Aleksandrova, V. R., S. A. Smirnova and V. M. Shubik. Ter. Arkh. 38(1):38-41, 1966.

A comparison was made of the results of titration of autoantibodies by Steffen's method and of the intracutaneous test with the autoserum of patients with hepatitis as indices of the allergic state of the body. The study was made on 295 patients (mostly aged 20-30 yr.) with epidemic and chronic hepatitis. Studies were made during the course of the disease and during the first yr. of convalescence. The blood of patients with epidemic hepatitis contained antibodies against liver cells. Positive intradermal test with autoserum was present in 76% of the patients, chiefly during the early stages of the disease. There was a definite correlation between the results of the intradermal test and the conc. of anti-liver antibodies in epidemic hepatitis. Among 216 studied, in 36 cases there was a positive dermal test and autoantibodies against liver cells were present in the serum; in 76 cases both indicators were absent; 61 cases showed positive intradermal test without presence of antibodies; in 42 cases the intradermal test was negative but anti-bodies were present. A positive reaction during the yr. of convalescence was preserved in 41 of 62 patients whose intradermal tests were markedly intense during the period of disease. Hormone therapy or novocaine block decreased the conc. of antibodies; symptomatic therapy had no effect on the positive and negative reactions. The intradermal test with autoserum became negative under the influence of hormone therapy.

- 6970 LYSOZYME, IN VIEW OF ITS PROTECTIVE EFFECT AGAINST INFLAMMATORY NECROTIC LESIONS OF THE LIVER, IN MICE INFECTED WITH HEPATIC VIRUS EFH-120. (Fr.) Brusca, A. E. (U. Messina, Italy), E. Comitini, C. Dionisi and P. Mastroeni. Med. Hyg. (Geneve) 24(721):154, 1966.

Following i.p. inoculation with 0.2 ml of rat liver homogenate infected with EFH-120 virus ($LD_{50} = 50$), Swiss albino mice were treated by i.p. inj. of lysozyme (5 mg every 12 hr. for 5 days). Histological examination of the livers of animals sacrificed at 24, 48, 72, 96, and 120 hr. after treatment revealed significant reduction with regard to both extension and intensity of EFH-120 virus-induced hepatic lesions including tumefaction, vacuolar degeneration, necrobiosis, hyperemia, edema, exudate formation and hemorrhage as compared to untreated controls.

- 6971 CONCENTRIC LAMELLAR FORMATIONS IN HEPATIC PARENCHYMAL CELLS OF CARBON TETRACHLORIDE-TREATED RATS. (E.) Stenger, R. J. (Cleveland Gen. Hosp., Ohio). J. Ultrastruct. Res. 14(3-4):240-253, 1966.

Female Holtzman rats received s.c. inj. of CCl_4 (0.4 ml of a 50% soln. in olive oil) twice a wk. Sustained admin. led to the development of hepatic cirrhosis. After admin. for 25 wk. parenchymal nodules appeared. Light microscopy revealed that these nodules contained groups of hepatic cells with intracytoplasmic, faintly laminated bodies (2-30 microns in diameter). Electron microscopy displayed these as concentric lamellar formations with myelin-like and fingerprint configurations. Both types consisted of multilayers of paired membranes, which were disposed concentrically about a core containing osmiophilic bodies. The peripheral membranes of

LIVER AND BILIARY TRACT

Viral Hepatitis

the formations frequently communicated with the smooth-surfaced endoplasmic reticulum of contiguous, partially depleted glycogen areas; however, structural continuity with the Golgi complex, plasma membrane, or perinuclear membranes was not observed. Previously reported lamellar bodies of similar structure have been the subjects of fundamentally differing interpretations. Present evidence favors the view that the CCl₄-induced lamellar structures represent new formations of endoplasmic reticulum. It is possible that these formations are concerned with detoxification.

- 6972 THE ACTIVITY OF "FREE" AND "BOUND" INSULIN IN THE BLOOD OF PATIENTS WITH ACUTE EPIDEMIC HEPATITIS. (Rus.) Leibush, B. N. Ter. Arkh. 38(1):41-47, 1966.

Insulin activity of the blood plasma of patients with acute epidemic hepatitis was assayed using the isolated rat diaphragm. Total insulin activity was determined gasometrically in the epididymal fat; insulin fractions (free and bound) were analyzed with the use of ion exchange resins. In normal subjects mean insulin activity (per ml of plasma) was 259 mm³; in patients insulin activity during the height of jaundice was 216 mm³, and during cure was 260 mm³. Therefore, the total insulin activity in all stages of hepatitis was within normal limits. The ratio between free and bound insulin was changed, with more free insulin found at the height of the jaundice and during convalescence. When known amounts of insulin were added in vitro to plasma, the plasma from patients showed much more activity than was expected; plasma from normals showed only slightly more activity. High activity of free insulin is due to disorders in the mechanism of binding insulin to proteins, as well as to the appearance in the blood of factors stimulating the activity of free insulin.

- 6973 COPPER, IRON AND ZINC CONTENT IN THE BLOOD SERUM OF PATIENTS WITH CHRONIC LIVER DISEASE. (Rus.) Korobochkin, L. M. (1st Order Lenin Inst. Med., Moscow). Ter. Arkh. 38(1):50-55, 1966.

A fluorescent method was used for the determination of copper and zinc and a colorimetric method was used for iron determination. The biological fluids of 52 patients with chronic hepatitis (32 epithelial type, 20 mesenchymal type) and 23 with fibrosis of the liver were analyzed for these trace elements. The serum level of the 3 elements was elevated compared to control levels but there were no significant differences between the groups of patients. A correlation exists between high copper content and the increased activity of alanine aminoferase. It is believed that a high copper content in the blood reflects activity of the pathologic process in liver parenchyma. There is a correlation between high zinc content and a moderate increase in serum cholesterol.

- 6974 CORRELATION BETWEEN IRON, COPPER AND MANGANESE IN THE BLOOD SERUM IN EPIDEMIC HEPATITIS (BOTKIN'S DISEASE). (Rus.) Zhernakova, T. V. Ter. Arkh. 38(1):59-65, 1966.

The study was made on 92 healthy women (controls) and 40 women with epidemic hepatitis of varying degrees of severity. At the height of disease the blood serum showed a marked increase in iron and a moderate increase in copper compared to controls; there was a decrease in manganese. During recovery from the acute phase and during convalescence, while there are some reductions in values, iron and copper values remained higher than normal while manganese levels remained below normal. At the height of disease the ratios of iron:copper and copper:manganese rose markedly. During recovery both ratios decreased but without reaching normal values; the iron:copper ratio showed the greater decrease. In epidemic hepatitis, as opposed to healthy subjects, there is a direct dependence between blood serum iron and copper, but not between copper and manganese. In infectious hepatitis there is also a direct dependence between the iron:copper ratio and serum bilirubin. Cortisone or prednisolone therapy had no predictable effect on serum copper and on the 2 ratios; blood transfusion decreased serum copper and had no reliable effect on the 2 ratios.

- 6975 EFFECT OF INFECTIOUS HEPATITIS ON THE IMMUNOGLOBULINS IN MENTALLY RETARDED CHILDREN. (E.) LoGrippe, G. A. (2799 W. Grand Blvd., Detroit, Mich.), H. Hayashi, N. Sharpless, B. Wolfram and R. Jaslow. J.A.M.A. 195(11): 939-942, 1966.

Serum immunoglobulins were determined in 60 institutionalized mentally retarded children (30 of whom were mongoloid) during a 3-wk. epidemic of infectious hepatitis. Immunoglobulins A (consisting of $7S_{\gamma 1}$ and β_2A), M ($19S_{\gamma 1}$ and β_2M), and G ($7S_{\gamma 2}$) were determined during the jaundice phase of the disease and 1, 4, and 7 mo. later; immune responses to 12 other enteroviruses (Coxsackie, polio, ECHO, etc.) were also determined during convalescence. In no case were immunoglobulin levels below normal at any time, and immunoglobulin A levels remained unaffected. Four patterns of immunoglobulin response were seen. In some patients (27-38%), both immunoglobulins G and M remained normal throughout. Immunoglobulin M and G values (the former indicating macroglobulinemia) were present during the jaundice phase of the disease in 22% and 13%, resp., of the children; 1 mo. later, these percentages were 9% and 28%, resp. This trend continued with time; 6-7 mo. later, immunoglobulins M and G were elevated in 4% and 42%, resp. Elevated levels of both enzymes were present in 38% during the acute phase and 26% after 6-7 mo. Macroglobulinemia and hypergamma-globulinemia persisted in 30% and 68%, resp., 6-7 mo. after the acute phase had subsided, even though the clinical signs had disappeared and the serum transaminases had returned to normal. From 10-14% of the children showed a persistent immunodepression; the 6 children with a poor immunoglobulin response also lost the ability (present during the first 1 mo. after onset) to synthesize antibodies against the other enteroviruses. There was no consistent relationship between the overall immune response and the levels of immunoglobulins M and G. The immune responses in the mongoloid children were about the same as those of the group as a whole.

- 6976 CONTRIBUTION TO THE STUDY OF IMMUNOCHEMICAL CORRELATIONS IN THE COURSE OF CHRONIC HEPATITIS. (Fr.) Zamfiresco-Gheorghiu, M. (Inst. Intern. Med., Bucharest, Rumania), C. Vlădescu, V. Runcan, T. Popesco, C. Miron and E. Grosu. Rev. Roum. Med. Intern. 2(4):299-305, 1965.

Serum immunoelectrophoretic studies (Scheidegger micromethod) as well as carbohydrate, protein, and lipid assays were performed in 18 normal subjects or patients without hepatic disease and in 52 patients with various hepatic diseases including chronic (40) or acute (5) viral hepatitis and cirrhosis (7). Among patients with chronic viral hepatitis, immunoelectrophoretic alterations (in relation to the analytical methods employed) included accentuation of the β_{2M} and β_{2A} arcs with concomitant increase of γ_2 -globulins (27.2-38%) in the majority of patients. Accentuation of the β_{2M} arc was more marked in the cirrhotogenic form and especially in splenic blood. Increased serum hexosamine levels and moderate but significant increase in sialic acid levels (d'Alaya method) were also observed in some patients. No correlation was possible between immunoelectrophoretic findings and the clinical form of chronic hepatitis.

- 6977 CHRONIC ANICTERIC HEPATITIS. (Cz.) Petera, V. (Charles U., Pilsen, Czech.). Plzen. Lek. Sborn. 25:135-144, 1965.

A total of 142 patients (69 men and 73 women; 26-82 yr. old) with chronic anicteric hepatitis were observed for 2-14 yr. (av. 6 yr.). Prior history, symptomatology, and clinical and laboratory findings are reported. Liver biopsy was performed in 94 of 142 and pathological changes were evident in one-third of the patients. These changes included fibrosis and changes in the size and number of nuclei and in staining properties of liver cells, but no cirrhotic changes.

- 6978 PSYCHIC DISTURBANCES IN PATIENTS WITH CHRONIC ANICTERIC HEPATITIS. (Cz.) Peterová, E. (Charles U., Pilsen, Czech.). Plzen. Lek. Sborn. 25:145-149, 1965.

Psychotic changes were noted in 42 of 142 patients with chronic anicteric hepatitis

and consisted mainly of disturbances of a neurotic-depressive nature. Carcinophobia occurred in 14 patients; one terminal hypoparanoic patient developed paranoid psychosis. Coincidental endogenous psychic disturbances were present in 2 women. No exogenous psychosis was observed. One man was a drug addict with psychopathic tendencies and committed suicide. Many of the patients' symptoms (nausea, vomiting, dyspepsia, anorexia, and others) may have been of psychogenic origin. Differential diagnosis is made with neurasthenia and endogenous depressions. Contrary to patients with endogenous depression, the present group had diarrhea instead of constipation and no daily rhythm of mood changes. Tranquilizers often diminished the depression and subjective disturbances of the patients in the present study.

6979 SOME COMMENTS ON INFECTIOUS HEPATITIS AMONG HEALTH WORKERS. (Cz.)

Houbal, V. (Purkyne U. Sch. Med., Brno, Czech.), Z. Latová and A. Voráčková. Cas. Lek. Cesk. 105(8):197-200, 1966.

From 1954-63, a total of 6745 patients with infectious hepatitis were treated at the University of Brno clinic; 341 of 6745 were health workers, among whom were 67 physicians, 167 nurses, 37 laboratory technicians, 7 dentists, 6 dental hygienists, 23 medical students, 15 students at health worker's school, 14 aids, 8 administrators, and others. The highest incidence of infectious hepatitis was seen among physicians and nurses of the surgical ward (25.3 and 22.7%, resp.), while the lowest incidence occurred in isolation wards for infectious diseases (0 and 2.7%, resp.). The long working hours, insufficient rest and sleep, exposure to disease, general sanitary conditions and habits are discussed as contributing factors toward the high incidence of infectious hepatitis among health workers. Since most were hospitalized much later than other patients, the course of the disease was usually more severe and prolonged.

6980 GAMMA GLOBULIN PROPHYLAXIS IN VIRAL HEPATITIS. RESULTS OF AN EPIDEMIOLOGICAL INVESTIGATION CONDUCTED IN ALGERIA IN 1959. (Fr.)

Hamon, Darbon and Colobert. Rev. Corps Sante Armees 7(1):111-121, 1966.

In November, 1959, in Algiers, military personnel were given prophylactic inj. of gamma globulin which were prepared at the Mustapha Hospital of Algiers, except on November 14 when gamma globulin prepared at the Army Transfusion Center (Lots 58/35 and 58/25) in Clamart, France, was inj. Among 660 subjects inj. with the latter type, 191 developed jaundice within 3 mo. Similarly, in Hussein-Dey, Algeria, no jaundice was observed in subjects inj. in May with gamma globulin of the Mustapha type, while 23% of subjects inj. on July 6 with Clamart gamma globulin and only 1.8% of those inj. with Mustapha gamma globulin on July 9 developed jaundice. On the contrary, at Bône, Algeria, inj. of 2 different military units with Mustapha gamma globulin resulted in the development of jaundice in 14 of 14 (100%) subjects of 1 unit and in only 1 of 15 subjects in the other unit. However, when 1,600 children of school age in France (outside of a viral hepatitis epidemic) were inj. with Clamart gamma globulin prepared during the same period (if not from the same lot) as the suspected type, no jaundice developed. From these contrasting observations, the authors conclude that the gamma globulin in question was not contaminated, and that the epidemic of viral hepatitis observed in November in Algiers was caused by hepatitis virus (virus A) and not by an inoc. virus (virus B).

6981 GUANASE ACTIVITY OF HUMAN SERUM IN VIRAL HEPATITIS AND OTHER HEPATIC DISEASES. (It.) Giusti, G. (U. Naples, Italy) and B. Galanti. Boll. Soc. Ital. Biol. Sper. 41(24):1567-1568, 1965.

Serum guanase was determined (Kalckar method) in 49 patients with viral hepatitis and 39 patients with other hepatic diseases including obstructive jaundice (12), bacterial angiocholitis (7), and cirrhosis (10). Serum guanase levels were similar in normal subjects (1.24 International U) and in patients with non-hepatitis diseases (1.08-1.39). Levels were markedly increased (22.11) in viral hepatitis patients. Results indicate a possible diagnostic value of serum guanase determination between hepatic diseases.

LIVER AND BILIARY TRACT

Viral Hepatitis

- 6982 STUDY OF THE FREQUENCY OF ANICTERIC EPIDEMIC HEPATITIS AS COMPARED TO THE ICTERIC FORM IN ISOLATED AND NON-ISOLATED GROUPS OF CHILDREN. (Fr.) Topciu, V. (Inst. Hyg., Timisoara, Rumania), G. Ciuhandu, O. Nevinglovski, N. Moisesco and L. Borbil. Arch. Roum. Path. Exp. Microbiol. 24(4): 1041-1054, 1965.

The incidence of anicteric hepatitis was studied among groups of children in permanent contact with (Group 1) and removed from contact with (Group 2) clinically confirmed cases of viral hepatitis. First determination of serum glutamic pyruvic transaminase (modified Wroblewsky-Cabaud-Domart method) showed higher percentages of positive response (more than 40 units) among children of Group 1 (14.8%) than among those of Group 2 (4.2%); a second determination (3-5 wk. later) showed a decrease in positive response in both Group 1 (5%) and Group 2 (2.5%); no positive response was noted in either group at the third determination (1 mo. after the second). Detection of high transaminase levels was possible at the first determination in 20 patients with no apparent disease among a total of 220 patients from both groups; of the 5 patients with positive response at the second determination, 4 were also positive at the first determination and 1 was negative. Of the 21 cases without jaundice, 1 developed jaundice 5 days after the first transaminase determination at which time high serum levels were found; of the other 20, 10 had various general symptoms including dyspeptic disturbances and hepatosplenomegaly, while 10 were asymptomatic. The higher incidence among children in Group 1 indicates the importance of prolonged contact in the spread of hepatitis.

- 6983 ETIOPATHOGENETIC ASPECTS CONCERNING THE EVOLUTION OF VIRAL HEPATITIS TOWARDS CHRONICITY, RESULTING FROM PROLONGED FOLLOW-UP. (E.) Lăzărescu, V. (Inst. Intern. Med., Bucharest, Rumania), C. Miron, I. Vasiliu, F. Ciobanu and V. Runcan. Rev. Roum. Med. Intern. 2(5):377-389, 1965.

Various etiopathogenetic factors in the chronic development of acute viral hepatitis were investigated in 959 patients (51.3% men and 48.7% women; most between 20-40 yr. old) with mild (22.8%), moderate (63.3%), or severe (13.9%) acute viral hepatitis. The duration of the acute phase was 2-6 wk.; in the 21-40 yr. age group, duration of the acute phase was 6.28 wk. in men and 4.45 wk. in women. Relapses and recurrences were more frequent in men (8.1% and 9.1%, resp.) than in women (4.1% and 5.1%, resp.). Progression to the chronic phase was observed in 52.2% of patients with severe acute viral hepatitis and in 24.3% of patients with mild or moderate acute viral hepatitis; approx. 25% of the patients presented an intermediate progressive phase of uncertain hepatic disease. Among 183 patients with no previous pathology or subsequent aggravating factors, 50% chronic progression and 23.5% cures were observed in those with severe acute form as compared to 23.1% chronic progression and 50% apparent cures in patients with the mild form. Severe and moderate acute forms were seen in 83.3% of patients infected by the parenteral route and 69.4% infected orally. Of the total group of 959 patients, 33.8% had no previous history of disease (12.3% of whom became chronic) and 62.2% had previous history of disease (30.5% of whom became chronic). Progression to chronic viral hepatitis occurred in 45.5% of patients with previous infectious disease (syphilis, tuberculosis, jaundice and others), 31.7% with previous metabolic disease (alcoholism; nutritional and hormonal disturbances), and 22.8% with previous gastrointestinal disturbances (gastroduodenitis, cholecystitis, colitis and others). Progression to chronic viral hepatitis was seen in 80% of patients with a past history of syphilis. Failure to observe proper diet and rest were aggravating factors in 76.5% and 75%, resp., of patients. Physical exertion influenced both the clinical form of viral hepatitis and its subsequent development.

- 6984 SERUM ENZYMES IN THE CHOLANGIOLYTIC FORM OF HEPATITIS. (Ger.) Ježek, P. (Purkyne U., Brno, Czech.) and J. Továrek. Zschr. Ges. Inn. Med. 21(4): 111-112, 1966.

Serum enzyme levels (expressed as μ moles except for alkaline phosphatase, which is

LIVER AND BILIARY TRACT

Viral Hepatitis

in King-Armstrong U) were determined in 3 groups (each 25 patients) of patients with the cholangiolytic form of infectious hepatitis (Group I), typical infectious hepatitis (Group II), and obstructive jaundice of various origins (Group III); patients with cholestasis of toxic or allergic origin were also included. Serum enzyme levels, tabulated as upper limits of normal, mean values in Groups I, II, and III, and (in parentheses) the number of patients in each group with elevated enzyme levels, were: glutamic-oxaloacetic transaminase, 1.5, 13.6 (23), 16.1 (25), 2.6 (12), resp.; glutamic-pyruvic transaminase, 1.5, 21.1 (24), 35.4 (25), 5.9 (18), resp.; aldolase, 0.55, 0.6 (18), 1.54 (23), 0.55 (10), resp.; sorbitol dehydrogenase, 0.1, 0.75 (24), 1.08 (25), 0.06 (4), resp.; isocitric dehydrogenase, 0.75, 2.06 (17), 3.2 (24), 0.76 (11), resp.; ornithine carbamyl transferase, 0.25, 0.32 (14), 0.48 (23), 0.25 (10), resp.; leucine aminopeptidase, 3.5, 5.1 (23), 5.4 (24), 3.99 (14), resp.; and alkaline phosphatase, 10.0, 28.0 (25), 12.6 (13), 32.6 (23), resp. In Group I, the enzyme patterns showed both the typical signs of hepatitis, comparable to those seen in Group II (increased indicator enzymes, especially the transaminases), and, on the other hand, enzyme levels indicative of obstruction (increased excretion enzymes, especially alkaline phosphatase). Determination of sorbitol dehydrogenase values seems especially valuable for the differential diagnosis of cholangiolytic hepatitis and true extrahepatic obstruction.

- 6985 EFFECT OF CHLOROQUINE ON LYSOSOMES AND ON GROWTH OF MOUSE HEPATITIS VIRUS (MHV-3). (E.) Mailucci, L. (St. Thomas's Med. Sch., London, S.E. 1). *Virology* 28(3):355-362, 1966.

Exposure of mouse peritoneal macrophages to chloroquine for 6 hr. with subsequent infection with mouse hepatitis virus led to a marked decrease in virus formation. When infected cells were incubated for 72 hr. after chloroquine treatment, the macrophages produced a higher yield of virus. Cytochemical investigations 3 days after chloroquine treatment showed an increased permeability of the lysosomes compared to studies performed immediately after treatment. Variations of the enzymes escaping from the lysosomes are thought to be responsible for differences in virus uncoating and consequent virus yield.

- 6986 CONTRIBUTION TO THE STUDY OF RESULTS IN PATIENTS WITH VIRAL HEPATITIS WITH OR WITHOUT CORTISONE TREATMENT. (It.) Bisiani, M. (Riuniti Hosp., Trieste, Italy), A. Konecny and R. Rolli. *Riv. Gastroent.* 17(4):137-147, 1965.

Among 60 patients with viral hepatitis (50% receiving prednisone along with regular treatment) who were followed for 1-4.5 yr. after hospitalization, response was considered favorable (no symptoms or subjective symptoms without objective symptoms or abnormal laboratory tests) in 33 (55%) and unfavorable (either severe subjective symptoms, objective symptoms, abnormal laboratory tests, or any combination thereof) in 27 (45%). Of the patients showing favorable response, 17 of 33 (51.5%) had received prednisone; of those showing unfavorable responses, 13 of 27 (48.5%) had received prednisone. The authors recommend the use of corticosteroids in the treatment of viral hepatitis.

- 6987 SERUM PROTEIN CHANGES DURING VARIOUS PHASES OF DEVELOPMENT OF EXPERIMENTAL HEPATITIS DUE TO MHV-3 VIRUS IN MICE. (It.) Piazza, M. (U. Naples, Italy), G. Manzillo, D. Lista and G. Pane. *Riv. Ist. Sieroter. Ital.* 41(1):1-6, 1966.

Serum protein determinations were conducted in 5-week-old mice inj. with MHV-3 hepatitis virus (1,000 LD₅₀) sacrificed 24, 48, and 72 hr. after inj. Total serum protein and α_1 -globulin levels were similar to those of uninfected controls. Serum albumin levels showed a marked decrease at 24 hr. and became lower as the disease progressed. A significant increase in α_2 -globulin and β -globulin levels was observed after 48 and 72 hr., resp. γ -Globulin levels increased significantly after 48 hr. Serum albumin/globulin ratio decreased significantly from hr. 24 on. The

change in serum levels of various protein fractions indicates hepatic damage (necrosis) caused by viral multiplication. The serum protein changes observed in this experiment during the acute phase of MHV-3 virus-induced hepatitis in mice are less marked than those observed in the subacute phase as reported in an earlier study. Similar differences were also observed in human viral hepatitis.

Cirrhosis

- 7010 RESULTS OF ELECTIVE PORTACAVAL ANASTOMOSIS IN 51 PATIENTS WITH PORTAL CIRRHOSIS AND BLEEDING OESOPHAGEAL VARICES. (E.) Baden, H. (Gentofte Hosp., Copenhagen, Denmark). Acta Chir. Scand. 131(1-2):60-71, 1966.
Elective portacaval anastomosis was performed in 51 patients with portal cirrhosis; all had experienced massive bleeding from esophageal varices. Operative mortality was 16%. At follow-up after periods from 3 mo. to 9 yr., 24 patients were alive. Late mortality was 44%; estimated 5-yr. survival was 33%. Postoperative gastrointestinal bleeding occurred in 18 patients; the most common causes were gastroduodenal ulcers and bleeding from varices owing to thrombosis of the anastomosis. Varicose bleeding occurred in only 1 patient with a functioning anastomosis. Neuro-psychiatric complications were noted in 60%, although these were severe in only 37% of the patients. Liver function, as indicated by fall of serum albumin level and sustained serum bilirubin level, appeared to be impaired by the operation in many patients. Thirty per cent of the survivors were able to resume their work in full or in part after the operation. There is evidence that elective shunt operations prolong survival, but as some one-third of the deaths in untreated series are attributable to bleeding varices, and since this can be prevented by a shunt operation carrying an operative mortality of less than 10%, the operation is indicated.
- 7011 HYPERPROTEINEMIA IN CIRRHOSIS OF THE LIVER. (Pol.) Jędrychowski, A. (Acad. Med. Cracow, Poland) and A. Wiernikowski. Pol. Arch. Med. Wewn. 35(1):53-59, 1965.
Among 61 patients with cirrhosis of 2-5 yr. duration, 11 (approx. 18%) showed hyperproteinemia. The 11 cases with cirrhosis and hyperproteinemia (Group I) and the 50 cases of cirrhosis only (Group II) were compared statistically with reference to plasma protein levels and clinical symptoms. In Group I, significantly higher levels of plasma proteins, α_1 -, α_2 -, and γ -globulins, and a higher incidence of splenomegaly (but no significant difference in incidence of hepatomegaly and ascites) were observed. It is concluded that the parameters listed above are of value in the differential diagnosis of cirrhosis with hyperproteinemia.
- 7012 OXYMETRIC STUDIES OF COLLATERAL CIRCULATION IN HEPATIC CIRRHOSIS. (It.) Perosa, L. (U. Bari, Italy), A. Pirrelli, L. Colonna and G. Brindicci. Mal. Cardio. 6(4):487-503, 1965.
Portal circulation as well as oxygen saturation in blood samples obtained from the femoral artery, cubital vein, and abdominal collateral circulation were measured in 17 patients with ascitic cirrhosis and 4 patients with portal stasis due to perihepatitis (1) or thrombosis of the hepatic (1) or portal veins (2). In cirrhotic patients, portal circulation was increased and oxygen saturation levels were higher in blood from the collateral circulation than in systemic venous blood (values were between those of systemic arterial and venous blood). In the other patients, oxygen saturation levels of blood from the collateral circulation differed only slightly from those of systemic venous blood. Results indicate the establishment in cirrhotic patients of a shunt between the hepatic artery and portal vein. The hemodynamic effects of this shunt are discussed.
- 7013 PAINFUL ONSET OF HEPATIC CIRRHOSIS. (It.) Sposito, M. (S. Giacomo Hosp., Rome) and V. Albertini Petroni. Policlinico [Prat.] 73(3):77-81, 1966.
Among 176 patients with cirrhosis, 20 presented with a painful symptomatology resembling biliary colic and 6 had a painful onset resembling acute abdomen. In 8 patients, the type of pain prompted explorative surgery. Several illustrative cases are presented. Possible mechanisms of painful onset include: acute distention of the liver capsule following congestion; inflammatory changes and thrombosis of the small intrahepatic portal vessels; transient biliary tract inflammation; possible acute pancreatic damage; hemodynamic alterations of portal pressure in the pre-ascitic phase of cirrhosis; accumulation of ascites.

- 7014 FATTY CIRRHOSIS IN THE RAT. XI. A HISTOCHEMICAL STUDY OF THE NODULES. (E.) Ohta, Y. (U. Minnesota Coll. Med. Sci., Minneapolis), F. G. Zaki and F. W. Hofbauer. *Arch. Path. (Chicago)* 81(4):317-324, 1966.

Male Holtzman rats fed a choline-deficient diet designated as CA6-38% developed 4 types of fatty cirrhosis: nodular, rapidly progressing nodular, slowly progressing nodular, and arrested nodular cirrhosis. Control animals received either normal diets or the experimental diet supplemented with choline. Enzymatic activity was compared in the nodules and adjacent original liver tissue. Enzymes used in the present study were succinic dehydrogenase, choline dehydrogenase, cytochrome dehydrogenase, β -hydroxybutyrate dehydrogenase, reduced nicotinamide adenine dinucleotide dehydrogenase, reduced nicotinamide adenine dinucleotide phosphate dehydrogenase, nonspecific acid phosphatase, and nonspecific esterase. Although differences were slight, they appeared to be consistent, distinctive, and related mainly to activities of succinic dehydrogenase.

- 7015 CORRELATION OF ANATOMICAL FINDINGS IN VARIOUS ZONES OF CIRRHOTIC LIVER. (Sp.) Orrego, H. M. (U. Chile, Santiago), M. Etchart, J. Espinoza and F. Tag. *Rev. Med. Chile* 93(11):689-697, 1965.

Morphological changes were compared and analyzed in samples of cirrhotic liver tissue obtained from 10 cadavers. Specimens were obtained from immediately below the capsule of the right lobe, the center of the right and left lobes, the hilar region, and the area adjacent to the gallbladder. Samples were analyzed by 2 skilled pathologists; lesions were tabulated and the degree of fibrosis was graded 0-4. Of the 10 lesions evaluated, the pathologists agreed on the degree of fibrosis, centronodular necrosis, fatty degeneration, appearance of intracellular bile, and presence of Mallory bodies. Results indicate that samples obtained from the center of the hepatic lobe give a good indication of hepatic alterations, while samples obtained from immediately below the capsule usually reveal a more severe degree of hepatic damage. No significant differences were observed when hematoxylin-eosin or Van Gieson staining methods were used. No correlation was found between fibrosis and other acute characteristics of acute liver damage such as necrosis, acute inflammatory infiltration, fatty infiltration, presence of Mallory bodies, or intracellular bile excretion. Slight correlation was observed between bile duct proliferation and fibrosis.

- 7016 II. DOSAGE AND DIFFERENTIATION OF URINARY AMINO ACIDS IN CIRRHOTIC PATIENTS BEFORE AND AFTER PORTACAVAL SHUNT. (Fr.) Ambert, J. P. (U. Paris Fac. Med., Sorbonne), C. Péchery, A. Lemonnier, E. Housset and L. Hartmann. *Ann. Biol. Clin. (Paris)* 24(1-2):41-50, 1966.

The dosage and differentiation of urinary amino acids by electrophoresis at pH 5.4, thin layer chromatography, and electrochromatography were performed in patients with cirrhosis before and after portacaval shunt. Av. amino-aciduria values (mg/24 hr.) and diuresis (liters) were 210 and 1.0, resp., in normal subjects, 500 and 2.22, resp., in patients with cirrhosis, and 495 and 1.55, resp., in cirrhotic patients after portacaval shunt. Normal patients showed a moderate increase in basic amino acids, valine, and tyrosine. In cirrhotic patients before portacaval shunt, markedly increased levels of ethanolamine, glycine, and α -alanine were observed; tyrosine and glycine were increased in 50%, cystine in 25%, while serine was decreased in 16%. Following portacaval shunt, cirrhotic patients showed an increase in ethanolamine and tyrosine and a decrease in serine; cystine and glycine levels were reduced; α -alanine, basic amino acid, and glutamic acid levels were frequently increased.

- 7017 LACKING INFLUENCE OF INFESTATION WITH Trichosomoides crassicauda ON THE DEVELOPMENT OF CIRRHOSIS OF THE LIVER IN RATS ON A LOW PROTEIN, HIGH FAT DIET. (E.) Ahlqvist, J. (State Alcohol Monopoly, Helsinki, Finland) and H. Borgmästars. *Acta Hepatosplen. (Stuttgart)* 13(2):111-114, 1966.

Two groups of male rats with initial wt. of 115-135 g were maintained on a low

protein, high fat diet for 201-221 days. During a period between 4-6 mo. of the diet, one group received repeated gastric instillations of fresh T. crassicauda containing viable eggs in their uteri. When the experiment was terminated, body wt. of controls was 288 g, that of infected animals 275 g. When the livers were graded according to the severity of cirrhosis, both control and infested livers exhibited about the same degree of involvement. Inflammatory lesions were found in the livers, they did not appear to be more common in the infected than in the control group.

- 7018 THE PRESENT STATUS OF SHUNTS FOR PORTAL HYPERTENSION IN CIRRHOSIS. (E.) Grace, N. D. (Tufts U. Sch. Med., Boston, Mass.), H. Muench and T. C. Chalmers. Gastroenterology 50(5):684-691, 1966.

Based on examination of data in 154 papers, the authors conclude that the risk of bleeding from esophageal varices is considerably reduced by a portacaval shunt. Despite this, survival, at least in the prophylactic group, is definitely not prolonged. Although early differences are evident, at the end of 4 yr. there is no significant difference between survival of patients undergoing elective therapeutic shunts and those shunted because their bleeding could not be controlled by conservative means. Hepatic encephalopathy appears to be increased after portacaval shunts. It is concluded that at the present time, it is still not possible to predict whether or not a given cirrhosis patient will benefit from surgical intervention.

- 7019 CIRRHOSIS AND HEPATOMA IN ALCOHOLICS. (E.) Lee, F. I. (London Hosp.). Gut 7(1):77-85, 1966.

The autopsy protocols of 84 cases of cirrhosis in alcoholics who died in the hospital between 1914-1963 were studied. Finely nodular cirrhosis was the commonest single morphological type, but half the cases had either coarsely nodular or postnecrotic cirrhosis. Patients who continued drinking to death were more likely to have finely nodular cirrhosis and those who gave up drinking some time before death were more likely to have coarsely nodular cirrhosis. Postnecrotic cirrhosis appeared not to be influenced by this factor. Hepatoma was common, occurring in 25 of the 84 cases (30%). Its occurrence was most closely correlated with increased age and, as in most reported series, was commoner in men. There was a high incidence of hepatoma in patients who gave up drinking some time before death and correspondingly coarsely nodular cirrhosis was the variety with the highest proportion of cases with hepatoma. There were 18 cases of postnecrotic cirrhosis, only one of which gave a history of viral hepatitis. Only 3 patients with post-necrotic cirrhosis had hepatomas (17.6%), the lowest incidence in the three morphological varieties.

- 7020 ERRONEOUS USE OF SPLENECTOMY AND PORTACAVAL ORGANIC ANASTOMOSIS IN PERICARDIAL PSEUDOCIRRHOSIS OF PICK. (Rus.) Sokolova, G. M. (Cent. Inst. Postgrad. Med. Train., Moscow). Vestn. Khir. Grekov. 96(1):126-130, 1966.

Among 30 patients with liver cirrhosis who exhibited ascites, 4 males (age 19-27 yr.) had Pick's pseudocirrhosis. Correct early diagnosis was made in 2 of the 4 cases. All 4 were subjected to splenectomy in combination with anastomoses of various organs, but without effect. In 2 patients who were severely ill, pericardiectomy was performed 2.5 and 3 yr. later, resp., with excellent results. Pericardiectomy was not performed in the remaining 2, although in one case the diagnosis of Pick's pseudocirrhosis had been made early; both died. All patients showed ascites, hepatomegaly, pleuritis or polyserositis, disturbances of blood circulation, heart changes, and persistent hypoproteinemia without change in liver function tests.

- 7032 INITIATING FACTORS OF GALLSTONES, ESPECIALLY CHOLESTEROL STONES. II. (E.) Hikasa, Y. (Kyoto U. Sch. Med., Japan), T. Kuyama, I. Maruyama, M. Yoshinaga, M. Hirano, T. Eguchi, R. Shioda, H. Tanimura, K. Hashimoto, H. Muroya and M. Togo. Nippon Geka Hokkan (Arch. Jap. Chir.) 34(6): 1430-1461, 1965.

Various conclusions have been drawn in an analysis of previous experiments on initiating factors in gallstone formation in rats and hamsters. Cholesterol stone formation was attributed to imbalance between the biosynthesis and degradation of cholesterol in the liver. This imbalance seems to be caused by a deficiency in pyridoxal phosphate and vitamin K₁ and K₂ which is produced by an abnormal shifting of the intestinal flora ("dysbacteria"). A greater absorption of animal fats containing saturated fatty acids and oleic acid, even without "dysbacteria", is a necessary condition for cholesterol stone formation in humans. Quantitative and qualitative changes in the total bile acids of bile are more important as a factor in cholesterol precipitation than changes in lecithin or its constituent fatty acids. Since the adrenal glands usually contain large quantities of essential fatty acids, a disturbance in the metabolism of the latter produces adrenal hypofunction which may also play an important part in the development of cholesterol stones. In experimental animals, pyridoxal phosphate or simultaneous admin. of higher unsaturated fatty acids and active vitamins afforded protection against cholesterol stone formation.

- 7033 THE EPIDEMIOLOGY OF GALLBLADDER DISEASE: OBSERVATIONS IN THE FRAMINGHAM STUDY. (E.) Friedman, G. D. (Heart Dis. Epidemiol. Stud., Framingham, Mass.), W. B. Kannel and T. R. Dawber. J. Chron. Dis. 19(3):273-292, 1966.

Longitudinal observations over a 10-yr. period on 5,209 inhabitants (2,873 women and 2,336 men; age 30-62 yr.) of Framingham, Massachusetts, have been used for a prospective investigation of the epidemiology of gallbladder disease. Diagnosis of gallbladder disease was "definite" (based on pathology reports, surgery, X-ray, and hospital admissions) in 427 and "doubtful" (based on physician's diagnosis with no further verification) in 116. Overall incidence of gallbladder disease was approx. twice that of men and increased with age in both sexes without evidence of excess at age 40. No relationship was seen between ethnic origin, serum cholesterol or hemoglobin levels, dietary fat, protein and cholesterol intake, level of physical activity, age at menopause, marital status, or precinct of residence and gallbladder disease. Increased incidence was seen in relation to wt. gain and number of pregnancies; women with lower systolic pressures showed a somewhat reduced risk, and slight negative correlations were noted between incidence and height and alcohol or cigarette consumption. No excess mortality was seen in patients with gallbladder disease, but it is not clear if such patients develop coronary heart disease at an excess rate.

- 7034 LOSS OF MAGNESIUM AFTER CHOLEDOCHOTOMY AND KERSCHER'S T-DRAINAGE. (Ger.) Wolff, H. (U. Leipzig, Germany) and W. Beier. Zbl. Chir. 91(7):239-243, 1966.

Daily determinations were made of the absolute amounts of electrolytes lost by postoperative drainage of gallbladder fistula in 12 patients undergoing choledochotomy followed by insertion of a Kersch T-drain. Postoperative electrolyte conc. in the bile flowing through the drain were also measured daily throughout the drainage period. Mean biliary conc. of magnesium, calcium, potassium, and sodium were 2.17, 6.43, 20.67, and 308 mg%/24 hr., resp. The av. total losses of these electrolytes during the 17-day drainage period were 120, 346, 1162, and 16,228 mg, resp. The need for electrolyte replacement during this type of treatment is emphasized.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

- 7035 THE CLINICAL DIAGNOSIS OF ANICTERIC OBSTRUCTION OF THE BILE DUCT. (E.) Kecalík, M. (Charles U., Prague, Czech.), P. Frič, A. Huslarová, F. Horáček, M. Kovárová and V. Friedberger. Gastroenterologia (Basel) 105(2):97-108; 1966.

Preoperative differentiation of intra- and extrahepatic obstruction of subjects with cholecystolithiasis (and normal extrahepatic bile ducts) and subjects with the syndrome of incomplete obstruction of the extrahepatic bile ducts was attempted on the basis of anamnesis, physical examination and various laboratory studies. In a total of 79 evaluable examinations by i.v. cholangiography, correct diagnosis (based on findings during operation) was obtained in 50.2% of the cases, inconclusive results were recorded in 37.6%, and incorrect results were obtained in 11.3% of the examinations. Elevation of serum alkaline phosphatase in 84 examinations led to correct diagnosis in 57.3% of the examinations. With sulfobromophthalein, using both retention time and time to appearance of dye in liver bile (obtained through use of a duodenal tube), the following results were obtained: correct, 50.6%; inconclusive, 37.6%; incorrect, 11.8%. With rose bengal, only the appearance time was studied; correct diagnosis was obtained in 13 of 21 examinations. Altogether, the correct preoperative diagnosis was established in 76.6% and incorrect in 11.1%; in 12.2% results were inconclusive.

- 7036 DIAGNOSIS OF CHOLEDOCHOLITHIASIS. RELATIONS BETWEEN HISTORICAL, LABORATORY, OPERATIVE, AND PREOPERATIVE ROENTGEN DATA. (E.) Almersjö, O. (Ekmanska Inst., Goteborg, Sweden), K. A. Hultborn and C. Jensen. Acta Chir. Scand. 131(1-2):112-126, 1966.

A series of 76 men and 244 women underwent 320 consecutive operations for treatment of gallstone disease during a 1-yr. period. One patient presented with acute cholecystitis and 4 with jaundice. Preoperative cholegraphy was performed in 313 cases. Stones were verified at choledochotomy in 39 cases; in 2 cases stones may have been displaced to the duodenum. Secondary postoperative cholangiography showed no stones in these 2 patients. A total of 45 choledochotomies were performed. The indication was founded on both clinical features and cholangiography during operation in 37 cases, on the basis of peroperative cholangiography alone in 7 cases, and on clinical evaluation alone in 1 case. In 7 cases peroperative cholangiography was carried out after choledochotomy. In these cases stones (mostly about 1 mm in diameter) were palpable in the choledochus but were not visualized by the initial peroperative cholangiography. In 7 cases peroperative cholangiograms were judged to be too poor to assist in finding stones. A retrospective analysis was made of 314 cases relating operative findings to the history and cholegraphic and laboratory findings.

- 7037 BILIARY TRACT DISEASES AMONG KOREANS. ANALYSIS OF 100 CONSECUTIVE CASES. (Kor.) Pyung Chul Min (Seoul Nat. U., Korea), Myung Ha Cho, Hun Myung Im, Ja Hoon Kim, Byong Ho Chin and Shim Suk Hahn. J. Korea. Surg. Soc. 8(2): 93-105, 1966.

An analysis is presented of 100 consecutive cases of biliary tract disease in Koreans. On chemical analysis, while all stones found were mixed, about half had cholesterol as the major component, and half bilirubin. Bilirubin content was greatest in hepatic duct stones. In 5 cases, 2 stones which were chemically and macroscopically different were found in the same patient at different locations. In contrast to findings in Caucasians, intrahepatic stones were found in 17% of the patients. Choledochal helminthiasis was seen in 10% of the cases. All were accompanied by moderate fever, positive bile culture and parasite eggs in the stool. Two-thirds of the cases also had stones in the biliary tract. Diagnosis of stone was indicated in 37% of studies utilizing plain abdominal films. The incidence of false negative cholecystograms was very high. Among 82 explorations of the common duct, stones were found in 64 cases. Common duct stones were more common than gallstones. Stones were found in 7 of 12 cases who underwent common duct exploration

although there were no prior indications of any pathology. Among 20 patients with stricture of the ampulla, 7 had common ducts of normal caliber.

- 7038 SIZE CHANGES IN THE GALLBLADDER WITH ORAL AND INTRAVENOUS CHOLECYSTOGRAPHY. (Ger.) Hemmati, A. (U. Bonn Sch. Med., Germany). Fortschr. Roentgenstr. 104(3):382-388, 1966.

Using flat plates of the abdomen, the size of the gallbladder was measured planimetrically after p.o. (Biloptin) and i.v. (Biligradin, Biligradin forte, or Bili-vistan) cholecystography in 92 patients. The max. interval between tests was 6 mo. (in 10 patients it was only 12 hr.); only those patients were included who showed no signs of liver or gallbladder disease in the intervening time period. Changes in small intestinal tonus were also measured by barium contrast studies, and an attempt was made to relate them to intestinal pressure changes and gallbladder size (following i.v. cholecystography). In these 92 patients, the av. surface area of the gallbladder shadow was 1710 planimetric U (not defined) after i.v. cholecystography and 2179 planimetric U after p.o. cholecystography, an av. difference of 27.6%. In the 10 patients undergoing both studies at a 12-hr. interval, the range of difference in gallbladder size using these methods was 20.4-35.5% (av. 28.2%). Barium contrast studies demonstrated a significant decrease in intestinal motility and tonus after i.v. cholecystography using Biligradin forte. In 1 patient, for example, there was no change in ileal or jejunal tonus after a barium study was begun; however, when i.v. cholecystography was performed a short time later, gallbladder filling was delayed and intestinal tonus was reduced.

- 7039 LITHIASIS AND LESIONS OF THE GALLBLADDER INDUCED EXPERIMENTALLY BY A MEDICATION, SODIUM DEHYDROCHOLATE. (Fr.) Besançon, F. (Bichat Hosp., Paris), C. Marche, M. Souhard and C. Debray. Bull. Soc. Med. Hop. Paris 117(2):127-138, 1966.

Female Swiss mice fed a normal diet to which sodium dehydrocholate (0.5%) was added developed cholesterol gallstones within 4 mo. Frequency of gallstone formation was about equal, if not slightly higher, in mice fed the same diet to which both cholesterol (1%) and sodium dehydrocholate were added. Mice fed diets to which cholesterol (1%) and cholic acid (0.5%) were added had a higher frequency of gallstone formation than those of the above 2 groups. In sodium dehydrocholate-treated mice, damage to the gallbladder mucosa was marked and included fat accumulation in the epithelium and chorion, atypical mucopolysaccharide inclusions, desquamation, and foci of inflammation. The liver was slightly hypertrophic and moderate steatosis was seen at microscopic examination. A pre-lithiasis phase was evident after 2-3 wk. in mice fed both cholesterol and cholic acid and in mice fed sodium dehydrocholate alone. Gallbladder alterations in this phase included increased fat and mucopolysaccharide accumulation in the epithelium, lymphatic vessels, and macrophages; lesions resembled those seen in cholesterosis. The lithogenic effect of sodium dehydrocholate even without cholesterol admin. is discussed.

- 7040 CHOLECYSTITIS AND STENOTIC ARTERIOSCLEROSIS. (E.) More, B. M. (Scripps Mem. Hosp., La Jolla, Cal.), W. F. Merdinger and S. C. Sommers. Am. J. Clin. Path. 45(4):465-467, 1966.

Vascular changes were investigated in 100 consecutive surgical cholecystectomy specimens classified pathologically as normal or with acute or chronic cholecystitis. The wall thickness and lumen diameter of small arteries were determined by measurement of their cross section with a microscope ocular micrometer. Both arteries and arterioles appeared to be irregularly thickened in gallbladders with cholecystitis. Arterial walls had thickened intimal layers characteristic of arteriosclerosis and, in relation to lumen size, were thickest (mean ratio = 2.25) in acute cholecystitis, next thickest (1.33) in chronic cholecystitis, and least

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

thick (0.66) in normal gallbladders. Regression coefficients (expressing the rate of change of wall thickness with change in lumen diameter) were somewhat similar in both groups of cholecystitis patients and significantly different in normal gallbladders. No significant statistical differences were found between the 3 groups with respect to age or blood pressure levels. Thus, stenotic arterial and arteriolar alterations in gallbladders with cholecystitis are more likely correlated with the presence of local disease. Localized arteriosclerosis and ischemia may predispose the gallbladder to bacterial or chemical injury and the development of cholecystitis.

- 7041 EXPERIMENTAL STUDY ON THE EFFECT OF METHOXYFLURANE ON THE TONE OF THE SPHINCTER OF ODDI AND COMMON BILE DUCT. (Fr.) Caillard, B. (28 Henri Gerard St., Bijon, France), S. Briet and J. Klepping. Ann. Anesth. Franc. 6(4):803-809, 1965.

The effect of inhalation of methoxyflurane in an open system on the sphincter of Oddi and common bile duct tone was studied in 10 dogs after insertion of a catheter into the common bile duct with or without nembutal and penthrane anesthesia. Intra-choledochus pressure curves for methoxyflurane were the same with or without pre-anesthesia and were identical to those obtained with amyl nitrite. No spasmodic effect on the sphincter of Oddi was seen; in fact, in several cases a spasmolytic effect on the hypertonia induced by morphine was observed. Contrary to ether, methoxyflurane failed to inhibit intestinal peristalsis.

- 7042 CLINICAL AND EXPERIMENTAL OBSERVATIONS ON THE PATHOGENESIS OF CHRONIC CHOLECYSTITIS. (Rus.) Shuia, N. A. Ter. Arkh. 38(1):75-79, 1966.

The author constructed a two-channel duodenal tube which permits collection of gastric contents without contamination of bile. In studies of bile in chronic cholecystitis, the bile periodically lost its colloidal stability and periodically there was formation of bile gravel. Eosinophils also appeared in the bile. In 18 patients with chronic cholecystitis, exacerbation of the disease could be demonstrated. The periodicity of the pathologic process, eosinophilia of biliary mucus and biliary hypersecretion served as the basis for the recognition of the allergic mechanism involved in the pathogenesis of this disease. In chronic experiments on dogs with surgically prepared biliary fistulae, cholecystitis was induced by Escherichia coli. During a period of 10 mo., none developed stones or significant amounts of gravel. The dogs then received 3 i.m. inj. (at intervals of 3-4 days) of homogenates of biliary tissues of healthy dogs plus dead intestinal bacteria. Ten days after the last inj. these dogs showed greater deposition of cholesterol, bilirubin and calcium as compared to control dogs which were inj. with liver homogenate plus bacteria.

- 7043 STUDY OF BILE, BILE FLOW, AND EXTRAHEPATIC BILIARY TRACT CHANGES IN CHOLECYSTECTOMIZED PATIENTS. (It.) Napolitano, A. (U. Rome), G. Tumino and E. Maggiore. Gazz. Int. Med. Chir. 71(8):651-666, 1966.

Investigation of bile, bile flow, and the extrahepatic biliary tract was conducted in 23 patients subjected to cholecystectomy 10 mo.-16 yr. previously. Of these, 3 had abnormally long cystic remnants, 1 of which resembled a newly formed gallbladder. Nine patients complained of dyspeptic disturbances or pain of biliary origin but no biliary colic or angiocholitic disturbances; disturbances were more frequent and marked in recently operated patients. Cholangiography revealed moderate dilatation of the common bile duct in 7 of 23 patients, among whom was only 1 of the 3 patients with abnormally long cystic remnants; the common bile duct was normal in the remaining 16 patients. Timed biliary duodenal drainage revealed no significant difference from that seen in patients with a gallbladder. Bile salt and pigment conc. was lower than normal in cholecystic bile samples, but normal in hepatic and common bile duct bile samples. Findings were similar in patients with an abnormally long cystic remnant. It is concluded that no compensating biliary

mechanism is provided for by the organism after cholecystectomy, and that this operation should not be performed unless warranted by gallstones, malignancy, or severe inflammation.

- 7044 RAMIFYING AND ADHESIVE MUCOSAL FOLDS OF THE GALL BLADDER. A CAUSE OF DISTRESS? (E.) Teir, H. (Distr. Hosp. Hyvinkaa, Finland), G. Elfving and T. Lehtonen. Acta Path. Microbiol. Scand. 66(3):327-330, 1966.
An examination was made of 53 gallbladders which appeared to be normal both macroscopically and microscopically. All of the patients had dyspeptic complaints; all but one had some kind of pain, but no severe episodes of pain were reported. Duration of symptoms ranged from 1 mo. to over 10 yr. In 51 patients, there were ramifying and adhesive folds within the gallbladder. In 23 cases the folds were very long and had grown together to form mostly a reticular structure. After follow-up of 1 mo. to 5 yr. after cholecystectomy, all but one were free of their pain; over 75% were free of all dyspeptic distress.
- 7045 EXPERIMENTAL STUDY OF CHRONIC SUB-PAPILLARY DUODENAL OBSTRUCTION AND ITS EFFECT ON THE BILIARY TRACT. (Fr.) Murat, J. (U. Lyon Fac. Med., France), J. L. Leclerc, J. L. Rodriguez-Alvarez and J. Feroldi. Bull. Soc. Int. Chir. 25(1):49-57, 1966.
Duodenal stricture below the papilla of Vater was induced in 26 dogs by ligature with an aponeurotic band; pyloric exclusion and gastroenterostomy were also performed. Follow-up of 20-120 days was possible in 14 dogs. Postoperative studies revealed acute dilatation of the duodenum and edema (approx. 12 days), followed by a chronic stage of moderate chronic dilatation and duodenitis with inflammatory and atrophic lesions; ulcerations occurred in some animals; papillitis usually appeared after 30 days. The gallbladder and common bile duct showed marked dilatation and increased pressure; histological alterations such as inflammation, sclerosis and mucosal desquamation were present; in 33%, biliary stasis and bile salt precipitation were observed. The liver showed congestion, edema, dilatation of hepatic ducts, and numerous angiocholitic abscesses around the capillaries. Similar changes were also observed in animals subjected to duodenal stricture and gastroenterostomy with or without bilateral vagotomy. Results are discussed in relation to late biliary tract complications frequently observed after gastroduodenal surgery.
- 7046 STUDIES ON CHOLECYSTOGRAPHY. II. EXPERIMENTAL STUDIES ON RETROGRADE CHOLECYSTOGRAPHY. I. (Jap.) Jibiki, A. (Toho U. Sch. Med., Japan). Nippon Igaku Hoshasen Gakkai Zasshi (Nippon Acta Radiol.) 25(8):1022-1032, 1965.

SUBJECT INDEX

Numbers followed by an asterisk (*) refer to abstracts in the text. Other numbers refer to citations only.

- Abdomen, acute, in pregnancy, diagnosis: 6385
- lupus erythematosus: 6384
- adhesions, due to surgical gelatin sponge: 6393
- radiation-induced changes: 6383
- swelling, treatment, rev.: 6388
- wounds, penetrating, diagnosis: 6386
- wall, desmoids: 6387
- Abetalipoproteinemia, lipoprotein and lipid transport: 6308*
- Abscess, anorectal: 6720
- perianal, in anorectal carcinoma: 6723
- Absorption, amino acids: 6099*
- and dietary source: 6097*
- and dipeptidases: 6130*
- and neomycin: 6122*
- and phlorhizin: 6116*
- rodent: 6129*
- amino acid transport, role of carboxyl group: 6105*
- and cetyltrimethylammonium bromide: 6123*
- disaccharidase levels: 6109*
- drugs: 6126*
- effect of mineral water: 6131
- fallout (real and simulated), human: 6127*
- fat, Chagas' disease: 6120*
- ferrioxamines: 6126*
- glucose and fluid, and inhibitors: 6115*
- glucose, glycine and NaCl, intestinal loops: 6103*
- and pregnancy: 6107*
- glutethimide: 6126*
- and intestinal blood flow: 6104*
- iron (Fe59): 6118*
- and pancreas: 6101*
- and phenylhydrazine: 6108*
- jejunum, mucosal histochemistry after gastrectomy: 6642*
- maltose, and nematode infection: 6189*
- neutral fat and fatty acid, effect of cholestyramine: 6121*
- Absorption, and pancreatectomy: 6186*
- and radiation: 6124*
- sodium: 6102*
- and glucose: 6114*
- goldfish: 6113*
- sugars, intestinal electrical activity disturbances: 6119*
- and temperature acclimatization: 6114*
- thalidomide: 6126*
- vitamin B12: 6100*, 6117*
- stomach, atrophic gastritis: 6468*
- and vitamin D3: 6067*
- Acetophenetidin, metabolism, liver: 6221*
- Acetylcholine, and colon muscle motility: 6209*
- receptors, intestine smooth muscle, and atropine uptake: 6106*
- Acetylsalicylic acid, gastric lesions, histochemical studies: 6463*
- and gastrointestinal lesions: 6303*
- Achlorhydria, with atrophic gastritis: 6468*
- Acid damage, and stomach mucosa fluid production: 6153*
- duodenal, and caffeine: 6579*
- secretion, and aldosterone or adrenalectomy: 6141*
- and caffeine and compound 48/80: 6149*
- and corticosteroids: 6169
- gastrin- or histamine-stimulated, after vagotomy, ulcer: 6132*
- and heparin, duodenal ulcer: 6577*
- and non-anticholinergic quaternary ammonium compounds: 6150*
- oral test meal technic: 6149*
- ulcer and gastritis: 6575*
- Adenoma, pancreas, islet cell, and acid secretion, Zollinger-Ellison syndrome: 6306*
- Adhesions, abdomen, due to surgical gelatin sponge: 6393
- and intestinal obstruction, surgery: 6527*
- Adrenal hormones, and gastric acidity and uropepsinogen: 6169
- Adrenalectomy, and cortisol, and liver glycogen synthetase: 6230*
- and gastric secretion: 6141*
- Adrenergic blockage, and colon muscle motility: 6209*
- Afferent loop syndrome, pathophysiology: 6633
- Aflatoxin, effect on liver, African child: 6928*
- Aflatoxin B1, hepatotoxicity, guinea pig: 6960
- Age, relation to hepatic storage and sulfobromophthalein secretion: 6234*
- to liver function after anticoagulant admin.: 6233*
- Alcohol, ethyl, and gastric mucosa: 6466*
- and liver porphyrin metabolism: 6919*
- toxicity, and liver metabolism: 6903*
- Alcoholism, chronic, liver octanoic dehydrogenase: 6924*
- with cirrhosis and hepatoma: 7019*
- Aldosterone, and gastric secretion: 6141*
- Allergy, and hepatitis: 6969*
- Amebiasis (see also under Parasites), indirect hemagglutination test: 6312*
- intestinal, chemotherapy, child: 6332
- dehydroemetine: 6331
- chronic: 6328
- liver: 6860
- biology and immunology, rev.: 6323
- clinical manifestations: 6324
- diagnosis, technic: 6326
- function tests: 6325
- therapy, rev.: 6327
- treatment: 6329
- clefamida: 6330
- Amino acids, absorption, and dietary source: 6097*
- and phlorhizin: 6116*
- serum, gastric disease: 6519
- transport, intestine, role of carboxyl group: 6105*
- urinary, and portacaval shunt: 6809*, 7016*
- α-Aminocaproic acid, therapeutic, experimental acute pancreatitis: 6768*
- Ammonia, blood, histopathology, subacute CCl4 intoxication: 6925*

- Amylase, pancreas, biosynthesis, and dietary starch or protein, rat: 6191*
 immunofluorescent localization in acinar cells, pig: 6143*
 serum, and inhibitory factor: 6190*
 acute pancreatitis, and heat: 6190*
 and lymphatic, after secretin stimulation, relation to age: 6145*
 Anabolic agents, and liver function, newborn: 6786*
 steroid, in gastroenterology: 6274
 and sulfobromophthaloin metabolism: 6842
 Anastomosis, biliopancreatic, experimental acute pancreatitis, technic: 6769*
 cholecystopancreatic, experimental pancreatitis: 6770*
 colorectal, by invagination: 6733
 intestinal, bleeding: 6391
 Anesthesia, nausea and vomiting, effect of Marophen: 6401
 Angiography, selective, gastrointestinal tract, dog: 6277
 Angiotensin, in liver diseases: 6816*
 Anorectal myotomy, and chronic fecal accumulation: 6671*
 Anorexia nervosa, plasma free fatty acids: 6299*
 Antibiotics, resistance, coli bacteria: 6296*
 dysentery bacteria: 6297*
 and typhoid fever carriers: 6309*
 Anticholinergics, comparative study: 6275
 Anticoagulants, liver function assay, age changes: 6233*
 Antihistamine (antazoline), and acid secretion: 6149*
 Antispasmodics, in radiology of large intestine: 6673
 Antrectomy, in duodenal ulcer: 6622
 Antrum, mucus: 6174
 Anus, anomalies, surgery, results: 6730
 external sphincter, cough response in paraplegia: 6285
 Anus, fissure, and irritable colon syndrome: 6670*
 imperforation, consequences of incomplete treatment: 6708
 pruritus: 6699
 tuberculosis: 6726
 Apparatus, colon biopsy: 6258*
 Gastrocamera: 6495
 early diagnosis of gastric cancer: 6464*
 pump for nasogastric feeding: 6260
 Russian suturing device: 6286
 Appendectomy, interval, perforated appendicitis: 6728
 Appendicitis, and enterobiasis: 6295*
 late pregnancy: 6727
 with lithiasis: 6734
 mucous membrane carbohydrates: 6729
 perforated, interval appendectomy, results: 6728
 Appendix, diverticulum: 6735
 perforation, incidence: 6736
 stainable iron and previous appendicitis: 6669*
 Arteriography, hepatic, with splenoportography: 6885
 Arteriosclerosis, stenotic, and cholecystitis: 7040*
 Arthritis, colitic, and ulcerative colitis: 6746*
 Assay, secretin, methods, selection of reference standard and rev.: 6142*
 Atherosclerosis, and liver and bile duct diseases: 6801*
 Atresia, anorectal: 6737
 esophagus, with gastrointestinal malformation: 6424
 management: 6427
 small intestine, relation to cystic fibrosis: 6537
 Atropine, effect on electrical stimulation of guinea pig ileum: 6208*
 and intestine smooth muscle: 6106*
 Autohistoradiography, gastrointestinal cancer, technic: 6416
 Azo dyes, toxicity, liver: 6950
 Azygos vein, and portal hypertension: 6789*
 Bacteria, intestinal, and Trichinella: 6291*
 Barium enemas, Indians and Africans: 6261
 3,4-Benzpyrene, and enzymes, liver microsomes: 6229*
 metabolism, liver: 6221*
 Beryllium, toxicity, liver: 6943
 Bile, alkaline phosphatase: 6792*
 Bile, and cholecystitis: 7042*
 7 α -dehydroxylation, fecal microorganisms: 6074
 effect on blood action against Salmonella: 6360
 excretion, and partial hepatectomy: 6247*
 flow, cholecystectomy: 7043*
 hepatic, electrolytes, and sulfonamides: 6243*
 human, and bilirubin sulfate: 6225*
 liver or gallbladder, micellar properties: 6242*
 'milk of lime', gallbladder surgery: 7077
 passage from bile duct lymphatics, hepatitis: 6913*
 secretion, and iodide: 6259*
 and sodium bicarbonate water: 6180
 Bile duct, common cystic dilatation: 7063, 7064
 effect of methoxyflurane on tonus: 7041*
 obstruction, experimental, and liver changes: 6812*
 palpation and exploration: 7048
 sphincter, evaluation of modifying surgery: 7054
 extrahepatic, physiology: 7058
 intrahepatic, surgical anatomy: 7050
 obstruction, anicteric, and preoperative diagnosis: 7035*
 and atherosclerosis: 6801*
 experimental, liver changes: 6812*
 and kidney function: 6244*
 Biliary tract, botryoid sarcoma: 7066
 disease, Korea: 7037*
 drainage, with electrolyte loss: 7034*
 effect of experimental duodenal stenosis: 7045*
 extrahepatic, after cholecystectomy: 7043*
 physiology and pathology: 7057
 intrahepatic shunt, technic: 6875
 obstruction, liver transaminase: 6805*
 secretion, γ -glutamyl transpeptidase: 6181

Biliary tract, stricture,
 repair: 7055
 surgery: 7049
 new diagnostic concepts, rev.: 7051
Billigrafin, high doses, in
 i.v. cholangiography:
 6877
Bilirubin, albumin-binding
 competition with sulfonamides: 6818*
 metabolism, effect of
 steroids, newborn:
 6786*
Bilirubin sulfate, chemical
 studies: 6225*
2,2'-Bipyridine, antisecretory
 effect, mechanism: 6138*
Blood coagulation, liver
 diseases: 6808*
6-Bromo-2-naphthyl- β -galactosidase activity, malabsorption syndrome:
 6645*
Budd-Chiari's syndrome, and
 splenoportography: 6796*
Butyrophenone derivatives,
 ulcerogenic effects:
 6583*

Cadaverine, and experimental
 cholera: 6298*
Caffeine, and gastric secretion:
 6149*
Calcium, deficiency, during
 biliary drainage: 7034*
Cancer, anorectal, with perianal
 abscess: 6723
 biliary tract: 7066
 cecum: 6739
 colon: 6709,6738
 ascending: 6686
 descending, upper:
 6685
 sigmoid: 6687
 common bile duct, with
 congenital absence of
 gallbladder and cystic
 duct: 7065
 duodenum: 6567,6568
 esophagus: 6460,6461,
 6462
 radiotherapy: 6457
 surgery: 6458
 rev.: 6459
 following gastrectomy:
 6615
 gastric stump, diagnosis,
 X-ray: 6518
 gastrointestinal, auto-
 historadiography,
 technic: 6416
 surgery and radiotherapy,
 results:
 6302*
 survival: 6415
 ileocecal region,
 radiology: 6696
 jejunum: 6566

Cancer, jejunum and ileum,
 primary: 6565
 radiology: 6563
 liver: 6892,6893,6895
 diagnosis: 6811*
 infant: 6896
 regional chemotherapy:
 6894
 scanning: 6881
 mesentery: 6382
 multiple, colon and rectum:
 6689
 familial: 6417
 pancreas, hypoglycemia in:
 6756*
 islet cell, and acid
 secretion, Zollinger-
 Ellison syndrome:
 6306*
 peritoneum, with asbestosis:
 6378
 rectosigmoid, prognosis:
 6691
 rectum, surgery, Bulgaria:
 6688
 salivary gland: 6371
 surgery: 6370
 stomach: 6515,6524
 cytology: 6513
 diagnosis: 6517
 tetracycline fluorescence:
 6516
 early, diagnosis, endoscopic:
 6467*
 Gastrocamera: 6464*
 late postgastrectomy effects
 on intestinal function:
 6508
 multiple: 6522
 pathophysiology and diagnosis:
 6512
 serum amino acids: 6519
 spontaneous, monkey: 6523
 surgery, radical: 6521
 results at 20 yr.:
 6520
 treatment, rev.: 6525
Carbohydrates, malabsorption, with
 ulcerative colitis: 6744*
 metabolism, liver, ethanol
 poisoning: 6903*
Carbon tetrachloride, cirrhosis,
 and parenchymal nodules:
 6971*
 liver damage, and enzyme
 changes: 6915*
 liver fibrosis, reversibility:
 6930*
 and liver phospholipids and
 nucleic acids: 6923*
 and liver and serum triglycerides:
 6911*
 metabolic effects, liver: 6931*
 toxicity, and free liver
 nucleotides: 6932*
 liver: 6946,6947
Carcinogenesis, 9,10-dimethyl-1,2-
 benzanthrane, intragastric:
 6307*

Carcinogenesis, liver: 6833
 20-methylcholanthrene,
 intragastric: 6307*
 N-nitrosomorpholine,
 liver, chromosome
 changes: 6917*
Carcinoidosis, rectum, statistics:
 6690
Cardiopulmonary disease, and
 gastroduodenal ulcer incidence:
 6582*
Cardia (see under Stomach)
Cardiospasm: 6428
 classification: 6428
 surgery, Gottshtein-Geller
 operation: 6472*
Catalase, in liver and transplantable
 hepatoma: 6831
Cecum, carcinoma: 6739
 mass, due to i.p. zirconium
 phosphate: 6716
Celiac disease, familial: 6650*
 jejunal lactate dehydrogenase
 isozymes: 6644*
Cells, ionic communication:
 6240*
Cell populations, dynamics:
 6077*,6082*
Cetyltrimethylammonium bromide
 (Cetrimide), and intestinal
 absorption: 6123*
Chagas' disease (see Trypanosomiasis)
Chloramphenicol, resistance,
 coli bacteria: 6296*
Chlordane, and enzymes, liver
 microsomes: 6229*
Chloroquine, and hepatitis
 virus growth, peritoneal
 macrophages: 6985*
Cholangiography, i.v., with
 Billigrafin: 6877
 surgical, method: 6878
 transhepatic, percutaneous:
 6879
Cholangitis, antibiotic sensitivity
 of bacterial strains: 7060
Cholecystectomy, biliary changes:
 7043*
 surgical findings: 7052
Cholecystitis: 7072
 acute gangrenous surgery,
 results: 7070
 surgery: 7053
 without gallstones:
 7069
 antibiotic sensitivity of
 bacterial strains: 7060
 galascorbin therapy: 7068
 pathogenesis: 7042*
 and stenotic arteriosclerosis:
 7040*
 and stone formation, allergic
 basis: 7042*
Cholecystography, after ipodate
 salts: 7047
 i.v. and p.o., comparison,
 normal human: 7038*

- Cholecystography, retrograde, experimental: 7046
- Cholecystokinins, and gall-bladder evacuation: 6199*
- and pancreozymin, and gastric motility: 6207*
- hog intestine mucosa: 6068*
- urinary, and magnesium sulfate: 6206*
- Choledochojejunostomy, recurrent choledocholithiasis: 7073
- Choledocholithiasis, diagnosis and surgery: 7036*
- Korea: 7037*
- socio-medical aspects: 7071
- surgery: 7073
- Cholelithiasis, accessory hepatic duct: 7075
- allergic pathogenesis: 7042*
- causing mechanical obstruction: 7076
- diagnosis and surgery: 7036*
- incidence, Korea: 7037*
- induced by sodium dehydrocholate: 7039*
- intrahepatic, rev.: 7074
- sodium dehydrocholate-induced: 7039*
- Cholera, Asiatic, clinical and biochemical study: 6364
- clinical studies: 6362, 6363
- clinical and bacteriological findings: 6365
- experimental, and pentamethylenediamine: 6298*
- Choleresis, and gastrin and histamine: 6154*
- Cholesterol, metabolism: 6250
- Cholestyramine, effect on neutral fat and fatty acid absorption: 6121*
- Chromaffin cells, and gastroduodenal ulcer: 6571*
- Chymotrypsin, assay, duodenal juice: 6176
- Chymotrypsinogen, biosynthesis, and dietary starch or protein, rat: 6191*
- immunofluorescent localization, acinar cells, beef pancreas: 6143*
- Cinchophen, effect on acid polysaccharides: 6580*
- Circadian rhythms, steroids, and liver disease: 6794*
- Circulation, collateral, cirrhosis, oximetric studies: 7012*
- micro-, and restraint ulcer: 6585*
- Cirrhosis, adrenocortical function: 7022
- and alcoholism: 7019*
- biliary, with toxic hypertrophic osteoarthropathy: 7031
- and blood groups: 7023
- and cardiomyopathy: 7025
- correlation of histological findings: 7015*
- corticosteroid treatment: 7027
- diagnosis, peritoneoscopy: 7021
- diagnostic value of hyperproteinemia: 7011*
- experimental, and nematodes: 7017*
- fatty, enzyme activity of nodules: 7014*
- hemochromatosis: 7030
- hydatid, therapy: 7026
- liver fatty acids in: 7029
- liver histochemistry: 7028
- macrocytosis: 7024
- oximetric studies of collateral circulation: 7012*
- painful onset: 7013*
- portal, and hemorrhage, and portacaval anastomosis: 7010*
- with portal hypertension, portosystemic shunt: 7018*
- pseudo-, Pick's syndrome: 7020*
- and serum polyenes: 6791*
- urinary amino acids, and portacaval shunt: 7016*
- Coccarboxylase, therapeutic, hepatic coma: 6815*
- Coenzyme A, metabolism, liver, ethanol poisoning: 6903*
- therapeutic, hepatic coma: 6815*
- Colchicine, intestinal mucosa, and dehydrogenases: 6158*, 6159*
- Cold, and lipid metabolism: 6237*
- lipotropic effects, rat liver: 6226*
- Colectomy, total, diverticulosis: 6706
- Colitis, chronic, with constipation, treatment, rev.: 6703
- Colon, aboral, dextrofixation: 6714
- anomaly: 6710
- ascending, cancer: 6686, 6695
- biopsy, technic: 6258*
- cancer: 6709
- carcinoma, spontaneous: 6738
- cleansing, sigmoidoscopy: 6675
- descending, upper, carcinoma: 6685
- diverticulitis, bleeding: 6705

treatment: 6701
Proelastase, secretion, pancreas, drug effects: 6139*
Prolapse, rectal, surgery, infant: 6724
Proteases, Pronase-P, intestinal absorption: 6128*
secretion, pancreas, drug effects: 6139*
Proteins, and amino acid absorption, intestine: 6097*
deficiency, and liver DNA: 6836
dietary, and amylase and chymotrypsinogen synthesis: 6191*
Proteolysis, and gastric secretion: 6185*
and gelatin test meal: 6652*
Proteolytic activity, pepsin, assay, colorimetric, technic: 6184*
Pruritus ani: 6699
changes in intestinal pH: 6700
primary, rev.: 6698
Pyloromyotomy, complete, without duodenal perforation: 6505
Pyloroplasty, duodenal ulcer: 6623
complications: 6629
gastroduodenal ulcer, complications: 6626
stomach diseases: 6477
stomach ulcer: 6612
with vagotomy, stomach ulcer: 6576*
Pylorospasm, acid-base balance, infant: 6490
Pylorus, congenital stenosis, incidence, Malta: 6483
and narcotic analgesics: 6198*
stenosis, acid-base balance, infant: 6490
Pyridine derivatives, antisecretory effect, mechanism: 6138*
Pyridoxine, intestinal, and bacterial flora: 6070*
Quaternary ammonium compounds, non-anticholinergic, screening, Shay rat: 6148*
Radiation, effect on Paneth cells: 6081*
and intestine transfer capacity: 6124*
and intestinal mucosa: 6086*
and pancreas enzymes: 6755*
and pancreas ultrastructure: 6755*
Radioactive fallout compounds, absorption: 6127*
Radioactive isotopes, liver size estimation: 6798*
Radioscanning, liver, metastatic carcinoma: 6811*
Reconstruction, esophagus, with dacron tube and dura mater covering: 6422*
Rectocolic area, surgery, suturing device: 6286
Rectosigmoid area, adenomatosis: 6692
Rectum, anomalies, surgery, results: 6730
atresia: 6737
carcinoidosis, statistics: 6690
carcinoma, pregnancy: 6694
surgery, Bulgaria: 6688
cleansing, sigmoidoscopy: 6675
ischemia: 6722
mucosa, protection during pelvic irradiation: 6676
polyps: 6682
malignant: 6684
prolapse, surgery, infant: 6724
sphincter, arrest, surgery: 6668*
surgery, continence preservation: 6731
tuberculosis: 6726

- Regional enteritis: 6638
and ulceroconstrictive disorders, intestine: 6530*
- Resection (see also under Surgery), antropylosic mucosa, gastroduodenal ulcer: 6617
pancreaticoduodenal, gastrointestinal cancer, survival: 6415
wedge, stomach ulcer: 6612
- Reserpine, toxicity, gastrointestinal: 6303*
- Restraint, and intestinal propulsion: 6212*
- Retina, stimulation, effect on gastric secretion: 6147*
- Ribonuclease, liver, developmental stages: 6222*
- Rifamycin, and liver mitochondria: 6929*
- Rotor syndrome: 6817*
genetic aspects: 6804*
- Saliva, agglutinins: 6075
composition, and pilocarpine: 6140*
electrolytes, cystic fibrosis: 6757*
- Salivary glands, diagnosis, sialography: 6377
enlargement, due to phyllosalaemin and isoprenaline: 6310*
and starch ingestion: 6375
hydatidosis: 6368
and immunosympathectomy: 6069*
inflammation, autopsy specimens: 6301*
RNA synthesis, and isoproterenol: 6133*
sarcooidosis: 6372
secretion, cytology, inflammation of buccal mucosa: 6376
surgery: 6374
thrombohemorrhagic lesions: 6373
tumors: 6371
mixed, surgery: 6370
zymogen granules, and fixatives: 6151*
- Salivation, and motor activity: 6135*
- Salmonella, action of blood against, effect of bile: 6360
antigenic conversion: 6357
- Salmonella enteritidis, infection, epidemiology and microbiology: 6359
streptomycin-resistant, experimental live vaccine immunization: 6292*
- Salmonellosis, cardiac changes: 6356
serological studies: 6358
vaccine, antigen lipid: 6353, 6354
- Schistosomiasis, diagnosis, fluorescent antibody technic: 6336
rectal biopsy: 6741
differential diagnosis of abdominal tumors: 6335
gastrointestinal, surgery: 6333
hepatosplenic, electrophoretic studies: 6866
liver blood flow: 6787*
incidence, school children, Rhodesia: 6334
liver fibrosis, and vascularization: 6806*
liver, portal hypertension: 6887
131I-triolein intestinal absorption test: 6870
susceptibility, suckling mice: 6337
treatment: 6338
- Scurvy, osteoporosis, and liver siderosis: 6813*
- Seasonal changes, duodenal and stomach ulcer: 6572*
- Secretin, assay, methods and reference standard, rev.: 6142*
and gastric motility: 6207*
and pancreatic protease secretion: 6139*
and serum and lymphatic amylase, age changes: 6145*
- Secretion, acid, gastrin- or histamine-stimulated, effect of vagotomy, ulcer: 6132*
histamine-induced, atrophic gastritis: 6475
tests: 6171
stomach diseases: 6494
antrum: 6162
biliary, γ -glutamyl transpeptidase: 6181
insulin, perfused pancreas: 6179
pancreas, protease, drug effects: 6139*
pancreatic β cells: 6178
pancreatic and biliary effect of sodium bicarbonate water: 6180
Shay rat, and non-cholinergic compounds: 6148*
stomach, and antrenyl: 6166
CNS control, rev.: 6167
comparison of s.c. histamine and histalog: 6172
and emulsified fat: 6204*
examination: 6164
- Secretion, stomach, and gastric inhibitory substance: 6136*
gastrointestinal diseases: 6146*
histamine dosage: 6183
influence of liver, pancreas, and duodenum: 6163
inhibition by 2,2'-bipyridine, mechanism: 6138*
mucosa, analysis, technic: 6165
and non-anticholinergic quaternary ammonium compounds: 6150*
and parathyroid hormone, ulcer: 6155*
and retinal stimulation: 6147*
and Spasmophen: 6173
stimulation and inhibition: 6161
- Selenium, carcinogenesis, liver: 6944
- Senecio (plant), hepatic toxicity, biopsy findings, horse: 6921*
- Serotonin, causing thrombohemorrhagic lesions: 6373
- Serum, alkaline phosphatase: 6792*
cholesterol esters, liver diseases: 6793*
enzymes, liver injury: 6961
variations, experimental liver trauma: 6927*
protein, experimental viral hepatitis: 6987*
binding competition of bilirubin and sulfonamides: 6818*
trypsin, diagnostic, chronic pancreatitis: 6771*
- Shelley test, Enterobacteriaceae antibodies: 6294*
- Shigella, injection, innocuous effect: 6343
- Shigellosis, incidence, Rumania: 6344
- Shock, hemorrhagic, and liver regeneration: 6248*
and portal vein bleeding: 6799*
- Shunt, biliary, intrahepatic, technic: 6875
- Siderosis, liver, and scurvy and osteoporosis: 6813*
- Sigmoidoscopy, preparation: 6675
- Sjogren's syndrome: 6366
child: 6367

- Sprue, tropical, therapy, sodium D-thyroxine: 6648*
- Stabilizers, and liver enzymes, rat: 6965*
- Starch, dietary, and amylase and chymotrypsinogen biosynthesis: 6191*
- Steatorrhea, diagnosis, D-xylose test: 6663
- Stenosis, duodenum, experimental, effect on biliary tract: 7045*
- esophagocardial, malignant, surgery: 6434*
- ileal, due to annular ulceration: 6547
- pyloric, congenital incidence, Malta: 6483
- Stomach, accessory pancreas in: 6764
- acetylsalicylic acid-induced lesions, histochemical studies: 6463*
- acid determination, new preparation: 6493
- acid polysaccharides, and cinchophen: 6580*
- Stomach, acid secretion, and aldosterone or adrenalectomy: 6141*
- comparison of histamine and histalog: 6172
- and heparin, duodenal ulcer: 6577*
- tests: 6171
- ulcer and gastritis: 6575*
- ulcer therapy: 6578*
- Vichy cure: 6170
- acid and uropepsinogen, and corticosteroids: 6169
- acidity, pathology: 6492
- activity, measurement, electrogastrographic: 6200*
- antrum, function: 6162
- atrophy, and intrinsic factor: 6473*
- biopsy, acute upper gastrointestinal hemorrhage: 6470*
- and secretion, gastrointestinal disease: 6146*
- cancer: 6515
- cytology: 6513
- early, diagnosis, endoscopic: 6467*
- Gastrocamera: 6464*
- multiple: 6522
- pathophysiology and diagnosis: 6512
- spontaneous, monkey: 6523
- surgery, radical: 6521
- results at 20 yr.: 6520
- treatment, rev.: 6525
- carcinogenesis: 6307*
- cardia, suction biopsy: 6446
- cooling and freezing: 6634
- corpus-antrum boundary, demonstration, technic: 6087*
- diseases, diagnosis, Gastrocamera: 6495
- HCl content tests: 6494
- duplication: 6481
- dystrophy, prevention, sumac: 6491
- effect of Baralgin: 6489
- function, atrophic gastritis: 6468*
- fundus gland, ultrastructure, and hypophysectomy: 6083*
- gastric stump carcinoma, X-ray diagnosis: 6518
- glandular, polysaccharides, and restraint: 6137*
- hemorrhage, with pheochromocytoma: 6482
- histamine levels: 6182
- histidine decarboxylase inhibition: 6182
- hydatidosis: 6484
- hypersecretion, results of magulson treatment: 6488
- hypoacidity, lipid absorption: 6640*
- Stomach, juice, gastric inhibitory substance from: 6136*
- protein, proctitis: 6702
- secretion, and hypothalamus: 6134*
- and splanchnicotomy: 6134*
- and vagotomy: 6134*
- lymphoreticulosarcoma, surgery and radiotherapy, results: 6302*
- micropolyps: 6486
- motility, action potential: 6216
- and duodenal mucosa extracts: 6207*
- electrical stimulation, technic: 6215
- and emulsified fat: 6204*
- and food and insulin: 6196*
- milk products diet: 6214
- mucosa, and alcohol: 6466*
- fluid production, and acid damage: 6153*
- metabolism, effect of hormones: 6168
- and restraint ulcer: 6585*
- technics of secretion analysis: 6165
- and urease activity: 6160*
- X-ray appearance, endocrine diseases: 6281
- parietal cells, stimulation and inhibition: 6161
- pathology, X-ray and clinical study: 6501
- proteolysis, and gastric secretion: 6185*
- rupture, and pyloric stenosis, after esophageal atresia surgery: 6423
- secretion, and cerebral loci stimulation: 6152*
- CNS control, rev.: 6167
- and emulsified fat: 6204*
- extravagal neural influences: 6152
- inhibition by 2,2'-bipyridine, mechanism: 6138*
- and iodide: 6259*
- and parathyroid hormone, ulcer: 6155*
- and proteolytic activity: 6185*
- and retinal stimulation: 6147*
- tests: 6487

- Stomach, stump, closure, wire staples: 6410
surgery (see also Gastrectomy), and early feeding: 6500
electrocardiogram and risks: 6511
tuberculosis: 6412
ulcerated neurinoma: 6524
volvulus: 6485
- Streaming potentials, gall-bladder wall: 6110*
- Streptomycin, and coli bacteria resistance: 6296*
- Stress, liver transaminases, infant and adult rat: 6910*
- Strongyloidosis, experimental, thiabendazole treatment: 6340
infant: 6341
- Substitution therapy, digestive enzymes, rev.: 6267
- Sucrose, intolerance: 6667
- Sulfobromophthalein, biliary excretion, and sparteine: 6235*
hepatic storage and secretion, age changes: 6234*
mathematical model of movement: 6241*
metabolism, and anabolic steroids: 6842, 6942
- Sulfonamides, albumin-binding competition with bilirubin: 6818*
and bile electrolytes: 6243*
and liver carbonic anhydrase: 6243*
- Surgery (see also Resection), abdominal, newborn, emergency: 6389
dumping syndrome, results: 6631
gastric, and early feeding: 6500
Gottshstein-Geller operation, cardiospasm: 6472*
Noble's plication, intestinal obstruction due to adhesions: 6527*
Wichmann's plication, intestinal obstruction due to adhesions: 6527*
Suturing device, Russian: 6286
Symmers' fibrosis, liver, vascularization: 6806*
Sympathomimetic agents, and gastric secretion: 6150*

Preface

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, cause, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from virtually every medical journal published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

PRE-CLINICAL SCIENCES

GENERAL

- 078 AN EXPERIMENTAL STUDY ON IRON METABOLISM IN MUCOUS MEMBRANE OF THE DIGESTIVE TRACT. (Jap.) Masuda, M. (Kyoto Pref. U. Med., Japan), S. Tanabe, N. Omae, M. Irie, K. Miyajima and K. Kozen. Kyoto Furitsu Ika Daigaku Zasshi (J. Kyoto Pref. Med. Univ.) 74(2):190-194, 1965.
- Iron metabolism was studied in rabbits following the intra-abdominal admin. of Fe^{59} ($25 \mu\text{C/kg}$). The existence of ferritin and hemosiderin in the mucous membranes of the digestive tract was indirectly demonstrated by a fractionation method. Although the iron content of the mucous membrane is small, its total amount in the whole digestive tract is considerable, suggesting an important role in depot iron metabolism. The turnover rate of radioactive iron in the mucosa of the gastrointestinal tract is much lower than that of the liver; the small intestine and bone marrow have similar rates; the stomach and large intestine have higher rates than the spleen. It is concluded that the gastrointestinal mucosa plays an important role in the absorption and excretion of iron and is one of the most important organs controlling iron metabolism.
- 079 HISTOCHEMICAL DEMONSTRATION OF CARBONIC ANHYDRASE ACTIVITY IN THE ALIMENTARY CANAL. (E.) Korhonen, L. K. (U. Turku, Finland), E. Korhonen and M. Hyyppa. Histochemie 6(2):168-172, 1966.
- Carbonic anhydrase activity in rat tissue was highest in the parietal cells of the stomach, followed by the colon epithelial cells, appendix, jejunum-ileum, duodenum, and esophagus, in decreasing order. Histochemical examination of gastrectomy specimens from gastric ulcer patients demonstrated an intense reaction in the parietal cells and a weak reaction in the pyloric glands. Carbonic anhydrase of rat or human origin had the same electrophoretic behavior as carbonic anhydrase from *Cl*, showing one rapidly moving band on a cellulose acetate film.
- 080 EFFECTS OF SYMPATHETIC VASOCONSTRICTOR FIBRES, NORADRENALINE AND VASOPRESSIN ON THE INTESTINAL VASCULAR RESISTANCE DURING CONSTANT BLOOD FLOW OR BLOOD PRESSURE. (E.) Dresel, P. (U. Goteborg, Sweden) and I. Wallentin. Acta Physiol. Scand. 66(4):427-436, 1966.
- The responses of the intestinal blood vessels of cats to electrical stimulation of vasoconstrictor fibers and to infused norepinephrine were about the same, and the "autoregulatory escape" was of about the same magnitude, when either pressure or blood flow was kept constant. The results suggest an increased submucosal blood flow at the expense of the mucosa; the similarity of the responses to constrictor fiber stimulation and to norepinephrine suggest a differentiated distribution of the vasoconstrictor fiber endings and the α -receptors in the intestinal bed. This hypothesis was supported by the well-sustained vasoconstrictor response without secondary adjustments produced by vasopressin.
- 081 EFFECT OF FASTING AND FEEDING ON LIPID METABOLISM OF PIGEON PANCREAS. (E.) Webster, P. D. (Duke U. Med. Ctr., Durham, N. C.) and M. P. Tyor. Am. J. Physiol. 210(5):1076-1079, 1966.
- The effect of fasting and feeding on lipid metabolism in the pancreas was determined in white Carneau pigeons (400-500 g, age 8-10 wk.) fed Purina pigeon grain *ad libitum*. Fasted pigeons were deprived of food 72 hr. before the study. Homogenates of pancreatic tissue from both groups were incubated with 1-C^{14} -palmitate for varying periods of time. The homogenates from fed pigeons showed a seven-fold increase in fatty acid oxidation compared to homogenates from fasted pigeons. Compared to the homogenates from fasted pigeons, those from fed birds showed a five-fold greater incorporation of the labeled palmitate into triglyceride and an enhanced incorporation into phospholipid. These changes most likely reflect the increase in metabolic activity of the pancreas with fasting.
- 082 THE EFFECT OF AMPICILLIN ON THE INTESTINAL FLORA OF THE HEALTHY MAN. (Ger.) Knothe, H. (U. Kiel, Germany) and B. Wiedemann. Zbl. Bakt. [Orig.] 197(2):234-243, 1965.

GENERAL

Daily stools were derived from 10 adult subjects during a 5-day period of peroral medication with aminobenzyl penicillin (ampicillin), 1-3 g/day; then daily stools for 7 days, followed by stools at intervals of 5-10 days as long as any possibility of continuing effect or counter-reaction seemed possible. *Bifidus* bacteria disappeared within 24 hr., then reappeared 2-4 days after medication was terminated. Enterococci, regardless of biotype, also disappeared within 24 hr.; reappeared in somewhat heightened conc. as soon as medication was terminated; were then normalized within a few days. *Escherichia coli* strains decreased progressively to total disappearance; reappeared shortly after treatment was ended, sometimes in the form of the same serotypes and sometimes in that of other serotypes. The Bacteroidaceae were diminished, but did not disappear. In some subjects, beginning medication was accompanied by initial appearance or a marked increase of Enterobacteriaceae (e.g., *Klebsiellae*, *Citrobacter*, *Aerobacter*, *Proteus vulgaris*, *Pr. morganii*, *Pr. rettgeri*, et al.), which disappeared gradually when medication was withdrawn. The effect on Lactobacteriaceae was not consistent and no effect was exerted on gemmiparous fungi.

- 7083 THE DECONJUGATION OF BILE SALTS BY HUMAN INTESTINAL BACTERIA. (E.) Drasar, B. S. (Cent. Middlesex Hosp., London, N.W.10), M. J. Hill and M. Shiner. *Lancet* 1(7449):1237-1238, 1966.

The capacity to deconjugate bile salts was studied in 97 strains of bacteria derived from the jejunal juice, feces, and saliva of healthy subjects (fasting and after food) or patients with various gastrointestinal diseases including steatorrhea. Of the species tested, only 15 of 25 strains of *Bacteroides* (*Fusiformis*) split bile conjugates; *Escherichia coli*, *Pseudomonas*, enterococci, and *Streptococcus salivarius* failed to do so. *Bacteroides* strains deconjugated bile salts both aerobically and anaerobically and those that split 1 conjugate could also split the other 3 conjugates. In contrast to the control group, the jejunal juice of patients with gastrointestinal disorders yielded abnormally large numbers of *Bacteroides*, and of the 14 strains tested from 10 patients, 9 deconjugated bile acids.

- 7084 PREVENTION OF EXPERIMENTAL ATHEROSCLEROSIS BY ILEAL BYPASS: 20% CHOLESTEROL DIET AND ^{131} INDUCED HYPOTHYROIDISM IN DOGS. (E.) Scott, H. W., Jr. (Vanderbilt U. Med. Ctr., Nashville, Tenn.), S. E. Stephenson, Jr., R. Younger, B. B. Carlisle and S. W. Turney. *Ann. Surg.* 163(5):795-807, 1966.

A surgical bypass of the distal 40% of the small intestine prevented the development of hypercholesterolemia and atherosclerosis in dogs despite their daily potent atherogenic regimen of 20% cholesterol dietary supplement, or the latter plus an inj. of ^{131} (0.5 mc i.p.). The av. serum cholesterol levels of these dogs ranged between 249-341 mg%, compared to 2 or 3 times this level in dogs without a bypass. In all dogs without the ileal bypass and on the atherogenic regimen, moderate atherosclerosis was found (generally in the aortic valve, abdominal aorta, and femorals). All animals received vitamin B₁₂ (50 µg/mo. i.m.), but despite this treatment the dogs with the bypass and the special diet gradually showed a serious wt. loss and tendency toward anemia.

- 7085 INTESTINAL ALKALINE PHOSPHATASE: REGULATION BY A STRAIN-SPECIFIC FACTOR IN MOUSE MILK. (E.) Nayudu, P. R. V. (Washington U., St. Louis, Mo.) and F. Moog. *Science* 152(3722):656-657, 1966.

- 7086 A POSSIBLE EXPERIMENTAL APPROACH TO THE ASSOCIATION OF HEREDITARY α_1 -ANTITRYPSIN DEFICIENCY AND PULMONARY EMPHYSEMA. (E.) Kueppers, F. (Rockefeller U., New York, N. Y.) and A. G. Bearn. *Proc. Soc. Exp. Biol. Med.* 121(4):1207-1209, 1966.

- 7087 CONVERSION OF p,p'-DDT TO p,p'-DDD BY INTESTINAL FLORA OF THE RAT. (E.) Mendel, J. L. (U. S. Food & Drug Admin., Washington, D. C.) and M. S. Walton. *Science* 151(3717):1527-1528, 1966.

- 7088 PHARMACOLOGICAL EVALUATION OF LIVER EXTRACTS. (It.) Preziosi, P. (U. Naples, Italy). *Boll. Chimicofarm.* 105(3):177-194, 1966.

GENERAL

- 7089 THE ANTIMICROBIAL ACTIVITY OF THE STOMACH CONTENTS OF SUCKLING RABBITS. (E.) Williams Smith, H. (Anim. Health Trust, Stock, Essex, England). J. Path. Bact. 91(1):1-9, 1966.

- 7091 EFFECT OF ANTIBIOTICS ON SOME RUMEN AND INTESTINAL BACTERIA. (E.) El Akkad, I. (Rowett Res. Inst., Bucksburn, Aberdeen, Scotland) and P. N. Hobson. Nature (London) 209(5027):1046-1047, 1966.
- 7092 ENTEROKINASE AND PHOSPHATASE CONTENT OF THE MUCOSA OF THE SMALL INTESTINE OF RATS GIVEN THERMALLY OXIDIZED SUNFLOWER OIL WITH THEIR FOOD. (Rus.) Zitler, T. N., M. N. Markova, M. Ia. Brents and N. A. Nazarova. Vop. Pitan. 25(1):40-44, 1966.
- 7093 EFFECT OF PANCREATIC PROTEINS ON INSULIN ASSAY SYSTEMS. (E.) Pruitt, K. M., B. R. Boshell and R. A. Kreisberg. Diabetes 15(5):342-345, 1966.
- 7094 CALF INTESTINAL 5'-NUCLEOTIDASE. (E.) Center, M. S. (Med. Coll. Georgia, Augusta) and F. J. Behal. Arch. Biochem. 114(2):414-421, 1966.
- 7095 DECREASE IN DRY WEIGHT OF THE SMALL INTESTINE IN ALBINO RATS FOLLOWING COMBINED TREATMENT WITH HEMATOPORPHYRIN AND PANIRRADIATION. (It.) Cittadini, G. (U. Siena, Italy). Boll. Soc. Ital. Biol. Sper. 42(5):234-236, 1966.
- 7096 DYNAMIC CHANGES IN THE TEMPERATURE OF THE SKIN, LIVER AND IN THE RECTUM DURING EXPERIMENTAL PYREXIA. (Rus.) Kadykov, B. I. and S. I. Liutinskii. Pat. Fiziol. Eksp. Ter. 10(2):10-14, 1966.
- 7097 STUDY OF THE RELATIONSHIP BETWEEN COLICINES AND VARIOUS ENTEROBACTERIOCINES. (Fr.) Hamon, Y. (Pasteur Inst., Paris) and Y. Péron. C. R. Acad. Sci. (Paris) 262(5) (Ser. D):581-584, 1966.
- 7098 AN IMMUNOCHEMICAL STUDY OF SERUM AND SOLUBLE LIVER AND SPLEEN PROTEINS IN THE RABBIT. (E.) Bednarik, T. (Inst. Haemat., Prague, Czech.). Physiol. Bohemoslov. 15(1):27-30, 1966.
- 7099 DETECTION OF HUMAN REAGINS BY SCHULTZ-DALE TECHNIQUE USING HUMAN APPENDIX. (E.) Chopra, S. L. (McGill U., Montreal, Quebec, Canada), B. A. Kovacs, B. Rose and L. Goodfriend. Int. Arch. Allerg. 29(4):393-396, 1966.
- 7100 ALTERATIONS IN SERUM PROTEINS FOLLOWING DELIPIDIZATION BY 2-OCTANOL. (E.) Miller, D. F. (Griffin Hosp., Derby, Conn.) and L. L. Waters. Yale J. Biol. Med. 38(5):410-416, 1966.
- 7101 IMMUNOCHEMICAL STUDIES OF SUBMICROSOMAL MEMBRANES FROM LIVER OF NORMAL AND PHENOBARBITAL-TREATED RATS. (E.) Lundkvist, U. (U. Stockholm, Sweden) and P. Perlmann. Science 152(3723):780-782, 1966.
- 7102 THE INFLUENCE OF LOW PROTEIN DIET ON THE COMPOSITION OF RAT LIVER CELL FRACTIONS. (E.) Harada, N. (Nagoya U., Japan) and S. Mogi. Agr. Biol. Chem. 30(3):274-277, 1966.

CELLULAR STRUCTURE AND MORPHOLOGY

- 7103 - DEVELOPMENT OF DIFFERENTIATION IN THE GASTRIC MUCOSA OF THE GOLDEN HAMSTER (Ger.) Arnold, M. (U. Tübingen, Germany). Zschr. Zellforsch. 71(1):69-93, 1966.

Two days antenatal the stomach of the golden hamster is lined with a single type of epithelial cell with loosely structured nucleus and cytoplasm and short microvilli on the luminal surface. Differentiation into parietal cells begins one day antenatal, when some of these develop long microvilli, anticipating inversion of the apical surface into the interior to form intracellular secretory capillaries soon after birth. It is completed by 4-6 days postnatal, with formation of a smooth endoplasmic reticulum, increase of mitochondria and increase of both succinic dehydrogenase and cytochromoxidase activity. Differentiation of muciparous cells also begins one day antenatal, with the apical appearance of mucoid granules in other parietal cells, first in the pyloric, then in the cardial and then in the fundic region. These cells become strongly period acid Schiff-positive. The mucus from pyloric and cardial glands remains neutral, as does that from all surface cells. However, beginning with day 2 postnatal, secondary cells which secrete acid mucus develop in the cervical part of fundic glands. When the differentiation of parietal cells is completed, the remaining, still undifferentiated, primary cells begin to develop into chief cells which can be identified as early as day 8 by their high RNA content. It is suggested that the progressive loss of glycogen observed during all of these differentiations may result from anoxidative breakdown of glucose into nucleic acid precursors and TPNH. The author also points out that with completion of the differentiation process (circa day 8 postnatal), parietal and chief cells react positively in terms of both succinic dehydrogenase and cytochromoxidase activity, while secondary and surface-epithelial cells react negatively.

- 7104 PLASTICITY OF VENOUS BED IN SMALL INTESTINE. (Rus.) Sopil'nik, A. Iu. (Ivano-Frankovsk Inst. Med., USSR) and N. A. Krasikova. Arkh. Anat. 50(2):60-65, 1966.

Plasticity of venous bed of the small intestine, following elimination of 2-4 intestinal veins combined with ligation of 1-2 marginal veins, was studied in 60 male rabbits (wt. 1200-2000 g); 10 of them served as controls. The duration of experiment was 2-90 days. Motor function of the small intestine under conditions of the impaired venous blood outflow was investigated in 12 acutely prepared animals. It was shown that ligation of the veins produced a distinct structural transformation both in the extraorgan and intramural veins of the intestine; they increase in their diameter and become convoluted. A large number of anastomoses and collaterals, particularly at the sites where a zone with impaired blood circulation continues into a healthy one, was observed. Motor function of the small intestine intensified immediately after elimination of its different veins and was slowed down within 40-60 min. after the operation.

- 7105 ELECTRON MICROSCOPY OF INTESTINAL MUCOSA. SOME NOTES ON TECHNIQUES. (E.) Pittman, F. E. (Queen Elizabeth Hosp., Birmingham, England) and J. C. Pittman. Arch. Path. (Chicago) 81(5):398-401, 1966.

After evaluating a number of technics in an attempt to establish a reliable and simple protocol for processing gastrointestinal mucosal specimens for electron microscopy, the authors present a simple and rapid method, previously used for skin for orientation of mucosal specimens. Described in detail are the obtaining of the specimen, fixation with glutaraldehyde, fixation with osmium tetroxide, dehydration, embedding, orientation of mucosal specimens, ultramicrotomy, and staining (saturated soln. of uranyl nitrate in absolute methanol followed by Millonig's lead tartrate stain).

- 7106 INTRAVITAL KARYORRHEXIS OF EXOCRINE PANCREAS CELLS UNDER THE ELECTRON MICROSCOPE. (Ger.) Altmann, H. W. (U. Würzburg, Germany) and P. Bannasch. Zschr. Zellforsch. 71(1):63-68, 1966.

Intravital karyorrhexis of the pancreas was produced in mice by admin. of atropine

CELLULAR STRUCTURE AND MORPHOLOGY

(0.2 ml of 1% soln., 2 inj. at a 4-hr. interval); 11 hr. after the second inj., the pancreas was removed for microscopic study. During karyorrhexis, the nuclear material separated into chromatin and karyolymph ("interchromatin substance"). Fixation of the tissues with either osmium or formaldehyde resulted in a similar nuclear picture in these cells, in contrast to the effects on normal cells. In the karyorrhectic cells, the chromatin was clumped into a dense cap associated with the nuclear membrane; the nucleolus, with relatively unchanged fine structure, was either isolated or associated with the chromatin "cap." The rest of the nucleus was occupied by the light karyolymph, which contained clearly visible interchromatin granules (diameter 200-250 Å), either isolated or in dense clumps. During later periods of karyorrhexis, the nuclear membrane sometimes remained intact but sometimes disappeared for variable periods of time. In the final stages, several chromatin clumps, partly enclosed within fragments of the nuclear membrane, were scattered irregularly within the cell. Cytoplasmic structures were affected slightly or not at all. These nuclear changes are attributed to dehydration of the DNA-carrying chromosome fibrils.

- 7107 OBSERVATIONS ON LOCATION AND ULTRASTRUCTURE OF DUODENAL LYMPHOCYTES. A LIGHT AND ELECTRON MICROSCOPIC STUDY. (E.) Landers, D. F. New Physician 15(6):137-141, 1966.

The fine structure of the lymphocytes located in the duodenal epithelium was studied by light and electron microscopy. In male rats, mice, and hamsters, an intercellular rather than intracellular localization of lymphocytes was observed. Lymphocytes were concentrated in the basal portion of the intercellular space, with 97% at the level of the epithelial nuclei or between the basement membrane and nucleus. Cytoplasmic pseudopodia were present, indicating active movement of the lymphocytes. Lymphocytes appeared to be in the process of migrating through the basement membrane, some from the epithelium to the lamina propria, and others from the lamina propria into the epithelium. No lymphocyte degeneration or mitotic activity in the villus epithelium was observed.

- 7108 ULTRASTRUCTURE AND HISTOCHEMISTRY OF THE GALLBLADDER MUCOSA OF MAN AND CAT. (Ger.) Wolf-Heidegger, G. (U. Basel, Switzerland), W. Stäubli and R. Hess. Acta Anat. (Basel) 63(4):606-618, 1966.

The gallbladder mucosal epithelium consisted of a single layer of cylindrical cells on a basal membrane, with microvilli projecting into the lumen and notched lateral membranes (implying fluid resorptive capacities), a polar Golgi complex, and numerous mitochondria and secretory granules, especially in the apical portion. In addition, the human gallbladder showed occasional clear cells, with a cytoplasm that appeared thickened by the presence of small agranular vesicles (especially apically) and free ribosomes (especially basally); these cells were not seen in the cat. Histochemical findings in both species were: neutral lipids in fine cytoplasmic droplets; a diffuse, faint phospholipid reaction; no cholesterol; acid mucopolysaccharides near the cell membranes; neutral mucin deposits in the supranuclear zone (some of which were diastase-labile and therefore glycogen-like); thiamine pyrophosphorylase in the Golgi complex; oxidative enzymes in the mitochondria; a possible lipase diffuse throughout the cytoplasm; and diffuse, weak glucose-6-phosphatase activity in the endoplasmic reticulum membranes. Marked alkaline phosphatase and nucleoside phosphatase activity was noted in the fenestrated endothelial cells of the capillary tunica propria. Enzyme reactions peculiar to the cat were a Golgi-bound indoxylesterase and mitochondrial adenosine triphosphatase. The Golgi apparatus of the human gallbladder epithelium also showed high acid naphthol phosphatase activity (possibly of lysosomal origin), but this was not seen in the cat.

- 7109 BILIARY REFLUX AND LIVER CELLS. ELECTRON MICROSCOPIC STUDIES IN THE RAT. (Ger.) Ehrenbrand, F. (U. Mainz, Germany) and F. Waldeck. Zschr. Anat. Entwicklungsgesch. 125(1):1-42, 1966.

After production of biliary reflux by cooling and retrograde (via the hepatic duct) instillation of bile and plasma mixed with mercury disulfide, resorptive changes were noted in the epithelial cells of the interlobular biliary canals. There were

CELLULAR STRUCTURE AND MORPHOLOGY

no ultramicroscopic signs of biliary reflux in these cells, but they did appear in the intercellular spaces of the liver. In the latter areas, the presence of desmosomes and dissolution of neighboring cell membranes argued against the presence of a preformed communication between the biliary canaliculi and either the venous liver capillaries or Disse's space. The pathway of biliary reflux was from the biliary canaliculi via the liver cells to the venous liver capillaries. The hepatocytes showed resorptive changes. An active transcellular reflux may have been present; intravital staining demonstrated bile particles in the form of cytosomes within the Kupffer cells. No preformed secretory pathways were demonstrated, but cells bordering the canaliculi showed diverticulum-like projections, apparently connected to cytoplasmic vesicles via the cytoplasmic β membranes.

- 7110 THE FINE STRUCTURE OF MUCOSAL EPITHELIAL CELLS OF A PATHOLOGICAL HUMAN GALL BLADDER. (E.) Chapman, G. B. (Georgetown U., Washington, D. C.), A. J. Chiarodo, R. J. Coffey and K. Wieneke. Anat. Rec. 154(3):579-615, 1966.

Electron micrographs were prepared of the mucosal epithelium of the fundus, body, and neck of a pathological human gallbladder immediately after surgical extirpation of the organ. Cells were found to be typical of epithelial cells in general; they contained microvilli, terminal bars, desmosomes, membrane interdigitations, Golgi apparatus, mitochondria, granular and agranular endoplasmic reticulum, and a nucleus delimited by a membrane interrupted by pores and containing one to several nucleoli. Three types of granules were observed: basal, predominately stellate-shaped granule of great density; apical, less dense, round or irregularly shaped granules; apical, least dense, usually round-shaped granules. The possible significance of these granules in relation to epithelial function and cholelithiasis is discussed.

- 7111 MUSCULAR STRUCTURE OF THE STOMACH WALL OF THE HUMAN FETUS AS COMPARED TO THE MUSCULAR STRUCTURE OF THE STOMACH WALL OF THE ADULT. (Ger.) Liebermann, D. (U. Freiburg i. Br., Germany). Jahrb. Morph. Mikroskop. Anat. 108(3) (Pt. 1):391-400, 1966.

In the human fetus, differentiation of the musculature into 3 layers was complete by the time the fetus was 75 mm long. The outer layer was a continuation of the longitudinal muscle fibers of the esophagus, following both curvatures in 2 thick sheaths and diverging on the side walls to form the apex of the fundus, which was free of any fasciculi of fibers derived from the stratum circulare of the corpus (but in whose formation the fibrae obliquae also took part). The innermost of the circular layers of muscle in the stomach was also derived from the esophagus, coming from the circular layer of muscle in that organ. In the pyloric region, the circular fasciculi of muscle fibers were replaced by a contractile network in which longitudinal muscle fibers were also distributed. The development of the fibrae obliquae, whose functioning is critically important to peristalsis, appeared to parallel the progressive expansion of the stomach from its original spindle form into a more flattened shape. The already-closed, outer rings of muscle tissue enlarged, while the innermost muscle tissues, lying directly next to the mucosa and stemming from the esophagus, adapted to the changing form of the stomach as they reproduced themselves. Thus new fibers developed, running in a progressively more latitudinal, rather than longitudinal, direction. Their varying lengths appeared to be determined by the relative time of their development; the shortest developing first, in the region of the fundus, and the longest developing last, at the caudal end of the corpus.

- 7112 RECONSTRUCTION OF INTRAHEPATIC VEINS IN A 13.5 mm HUMAN EMBRYO. (Fr.) Kamina, P. (U. Bordeaux Sch. Med., France), M. J. Ellie, J. Videau and Y. Rideau. C. R. Assn. Anat. 50(132):553-558, 1966.

- 7113 ARTERIAL BLOOD SUPPLY OF THE COLON IN AN AFRICAN NEWBORN OF THE IVORY COAST. (Fr.) Le Guyader, A. (U. Abidjan Sch. Med., Ivory Coast), K. Kerech, C. Delteil and M. Laigo. C. R. Assn. Anat. 50(132):653-662, 1966.

CELLULAR STRUCTURE AND MORPHOLOGY

- 7114 MORPHOLOGICAL AND HISTOCHEMICAL ALTERATIONS IN MUCOSA OF STOMACH AND DUODENUM AFTER HYPOPHYSECTOMY. (Rus.) Lipovskii, S. M. (Inst. Sanit. Hyg. Med., Leningrad, USSR), N. M. Zhukova and A. Sh. Zaichik. Ark. Anat. 50(2):34-39, 1966.

ABSORPTION

- 7124 COMPARATIVE MORPHOLOGY OF THE INTESTINAL MUCOSA OF TWO ANIMAL SPECIES WITH REGARD TO DIFFERENT POSSIBILITIES OF NEONATAL PROTEIN ABSORPTION. (Fr.) Kraehenbuhl, J. P. (U. Lausanne, Switzerland), E. Gloor and B. Blanc. Zschr. Zellforsch. 70(2):209-219, 1966.

The comparative morphology of jejunoileal segments of rat and rabbit intestinal epithelium was studied by light and electron microscopy. The structural features and development of absorptive cells were similar in both species despite functional differences in neonatal protein absorption, the rat being capable of absorbing protein (antibodies, for example) while the rabbit does not show any transfer upon p.o. admin. of antibodies. In both species, the structure of intestinal absorptive cells of the fetus at term and of the newborn from day 1 to day 20 showed marked development. In fetal cells, the apical portion of the space between the nucleus and terminal web presents a well-developed smooth endoplasmic reticulum. This reticulum is progressively replaced from the first days of life by numerous, large vacuoles which diminish in size and number from day 10 until their disappearance on day 20, at which time they assume adult characteristics.

- 7125 EFFECTS OF ADSORBENTS ON DRUG ABSORPTION. II. EFFECT OF AN ANTIDIARRHEA MIXTURE ON PROMAZINE ABSORPTION. (E.) Sorby, D. L. (U. California Med. Ctr., San Francisco) and G. Liu. J. Pharm. Sci. 55(5):504-510, 1966.

In an in vivo study (one subject), the presence of an antidiarrhetic mixture containing activated attapulgit, colloidal activated attapulgit and citrus pectin interfered demonstrably with the absorption of test doses of promazine hydrochloride from the human gastrointestinal tract, as reflected in urinary excretion samples. Both the overall amount absorbed and the rate of absorption were reduced; presumably due to the adsorptive qualities of the antidiarrhetic and its affinity for the drug, as demonstrated in vitro. The authors point out the probability that effects would be essentially similar for other amines of similar basicity and adsorbability in vivo.

- 7126 ABSORPTION OF C^{14} -LABELED LIPIDS IN NORMAL RATS AND IN RATS WITH BILIARY FISTULA. (It.) Cesano, L. (U. Turin, Italy). Boll. Soc. Ital. Biol. Sper. 42(5):208-210, 1966.

The absorption of C^{14} -labeled triolein or oleic acid was studied in normal rats subjected to laparotomy and rats with biliary fistula. Lipids were admin. by stomach tube in doses of 0.2 ml (1 μ c of radioactivity) 24 hr. after surgery. Triolein absorption was 73% of the admin. dose in normal animals and 32% of the admin. dose in animals with biliary fistula. Oleic acid absorption was 75% of the admin. dose in normal animals and 22.5% of the admin. dose in animals with biliary fistula. Since small quantities of the admin. dose remained in the stomach, the percentages of absorption can be considered slightly higher. The percentage of absorption is lower than that reported by other authors, possibly due to differences in the quantity and mode of admin. of the lipids.

- 7127 TIME COURSE AND NATURE OF TEMPERATURE-INDUCED CHANGES IN SODIUM-GLUCOSE INTERACTIONS OF THE GOLDFISH INTESTINE. (E.) Smith, M. W. (A.R.C. Inst. Anim. Physiol., Babraham, Cambridge, England). J. Physiol. (London) 183(3):649-657, 1966.

Glucose-evoked potentials of incubated goldfish intestine were highly temperature dependent at low temperatures (Phase I, 8°C) but less so at high temperatures (Phase II, 25°C). The transition temperature from Phase I to Phase II was approximately equal to the temperature at which glucose began to raise the steady intestinal transmural potential. No changes in intestinal electrical parameters could be found when fish, acclimatized to 8°C, were heated to 25°C for 15 hr., but after 20 hr. at 25°C, acclimatization to 25°C was complete. Intestines from fish acclimatized to 8°C but which had spent 15 hr. at 25°C and then 10 hr. at 8°C still behaved qualitatively like intestines at 8°C but the magnitude to the glucose-evoked potentials was slightly reduced. It is postulated that acclimatization of the

ABSORPTION

of the sodium-glucose interaction to different environmental temperatures involved the synthesis of new carrier molecules qualitatively different from the old ones.

- 7128 MINERAL COMPOSITION AND RATES OF FLOW OF EFFLUENT FROM THE DISTAL ILEUM OF LIQUID-FED CALVES. (E.) Smith, R. H. (Nat. Inst. Dairy Res., Reading, Berkshire, England). *J. Physiol. (London)* 183(3):532-550, 1966.

Liquid-fed calves, 1 1/2-4 mo. old, at more than 5 wk. after insertion of a re-entrant fistula into the distal ileum, with normal sodium and potassium without abnormal gut infection, had mean ileum emergence rates of 2.3 mM/hr. Na, 0.38 mM/hr. K and 21 g/hr. water at 16 hr. after fasting. Na and K emergence rates were similar to fasting rates after milk or glucose soln. feeding. Varying Na or K intake did not change ileal emergence rates; however Na or K deficient diets did change the Na/K ratio of the ileal effluent. An increase in Na and K emergence rates which occurred at 3 mo. was due to infection and could be prevented by aureomycin. Water emergence rate reflected changes in the emergence rates of osmotically effective constituents and isotonicity was maintained. After fasting, Na and K conc. were constant at 132 mM/liter. After milk or glucose, magnesium chloride soln., the Na + K conc. was depressed and Na + K + 1.5 Mg conc. was approximately constant at 139 mM/liter. Mg acted as if it were mainly ionic while calcium had no apparent osmotic effect. Bicarbonate was the major anion in the ileal effluent after milk feeding.

- 7129 THE SURFACE AREA OF THE INTESTINAL MUCOSA IN THE LACTATING RAT. (E.) Boyne, R. (Rowett Res. Inst.; Bucksburn, Aberdeen, Scotland), B. F. Fell and I. Robb. *J. Physiol. (London)* 183(3):570-575, 1966.

The mucosal and serosal surface dimensions of the rat duodenum, jejunum and ileum were obtained by measurements of photographs of histological sections and the surface areas calculated. The estimated mucosal surface area of virgin rats (240-280 g) per unit length of serosa (cm²) was 5.40 for duodenum, 7.07 for jejunum and 5.69 for ileum. On the day 16 of lactation the values were 10.75 for duodenum, 12.32 for jejunum and 9.67 for ileum showing that the mucosal area/unit length of serosa was appreciably increased during lactation. The mucosal area/serosal area ratio was also markedly increased but to a lesser extent distally, where an important component of the intestinal hypertrophy was dilatation of the intestine.

- 7130 STUDIES ON ELECTROLYTE ABSORPTION IN THE INTESTINE. (E.) Yoshitoshi, Y. (U. Tokyo Fac. Med.). *Jap. J. Med.* 4(4):288-291, 1965.

Ouabain inhibited the ability of sodium and potassium ions to activate adenosine triphosphatase in microsomal fractions of intestinal mucosa derived from the small intestine of the guinea pig and incubated with sodium, potassium and/or magnesium chloride. During incubation in cold Krebs-Ringer-phosphate soln., mucosal slices lost potassium and gained sodium ions, an effect which was completely reversed during incubation at 37°C under aerobic conditions. Ouabain also inhibited this spontaneous reversal, as well as the ability of the slices to take up radioactively marked rubidium. All three inhibitions were max. at a conc. which reduced mitochondrial respiration (controlled by adenosine diphosphate derived from adenosine triphosphatase) by approx. 35%. Studies of an everted sac preparation appeared to indicate that the unidirectional flux of sodium ions across the intestinal mucosal cell was controlled primarily through the basal membrane in contact with the perimucosal fluid, rather than that which was in contact with the lumen. Addition of ouabain to the medium exerted only a negligible inhibitory effect. The author concludes that adenosine triphosphatase activated by sodium and/or potassium ions is closely related to the active cation transport involved in the maintenance of ion gradients within the intestinal mucosal cell, and also in the transport of salt (usually, sodium chloride) and water across the cell.

- 7131 CHOLINESTERASE ACTIVITY AND SULFONAMIDE ABSORPTION IN RATS. (E.) Green, V. A. (U. Missouri Sch. Pharm., Kansas City), T. M. Glenn, S. J. Strada and G. Medina. *J. Pharm. Sci.* 55(5):516-517, 1966.

In rats receiving peroral sulfacetamide, sulfanilamide or sulfaguanidine, simultaneous admin. of neostigmine methylsulfate resulted in significant increases of

ABSORPTION

4-hr. blood sulfonamide levels (particularly in animals receiving sulfanilamide) and a mean decrease of blood cholinesterase activity by 20%. The authors suggest that these data may indicate some combination of anticholinesterase with the enzyme as a part of cell membrane in the intestinal tract, resulting in changes of the characteristics of the membrane which permit increased permeability.

- 7132 A SIMPLIFIED METHOD OF INDUCING STOMACH ULCERS. (E.) Mikhail, A. A. (Maudsley Hosp., London, S. E. 5) and H. C. Holland. *J. Psychosom. Res.* 9(4):343-347, 1966.

Gastric ulcers were induced in MNR strain male rats by application of a plaster of Paris corselet around the abdomen and lower thorax; the device was held in place by rubber bands. The animals were fasted for 12 hr. before application of the corselet. No gastric ulcers developed in fasted rats not bearing the corselet. In the experimental group there were no ulcers after 12 hr. of wearing the corselet, but after 24 and 36 hr. the ulcer incidence was 75% and 50%, resp.; the mean number of ulcers/rat after 24 and 36 hr. was 1.75 and 1.00, resp. The mean number of ulcers could be increased to 3.0 after 24 hr. of wearing the corselet, if the animals were fasted for 20 hr. before the stress period. Ulcers developing after 24 hr. were usually confined to the antrum, appearing as discrete, circular white areas less than 1.5 cm in diameter. After 36 hr. of stress, hemorrhagic erosions about 2 mm in diameter were noted in the corpus; they were circular and easily counted and measured. In addition to the uniformity of ulcers produced by this method, several other advantages are mentioned: the apparatus is prepared in advance and can be applied and removed by one person without assistance; drugs can be admin. i.p. while the corselet is in position; the corselet's diameter can be individually adjusted; and restraint of the animal's movement during the stress period is unnecessary.

- 7133 Ca AND Mg LEVELS IN GASTROINTESTINAL MUCOSA OF FED, FASTED AND LACTOSE-TREATED RATS. (E.) Marcus, C. S. (New York State Vet. Coll., Ithaca) and R. H. Wasserman. *J. Appl. Physiol.* 21(3):1063-1067, 1966.

There was no significant shrinkage, swelling, or change in water content of mucosal cells of the rat gastrointestinal tract (stomach to ileum) after fasting or lactose admin., as compared to normally fed animals. Mucosal calcium was decreased somewhat by fasting and even more so by lactose admin.; these differences were significant at the 95% and 99% confidence levels, resp. Calcium conc. was higher in the proximal than the distal portions of the small intestine. Mucosal magnesium conc. was increased by both fasting and lactose treatment (same degrees of significance as above). Plasma calcium and magnesium conc. was unchanged in fasting animals, but decreased after lactose admin. There was no significant difference in total alkaline earth conc. in pooled mucosa of fed, fasted, or lactose-treated rats, but the calcium:total alkaline earth ratio was decreased by fasting and lactose, especially the latter. The number of cells/mg tissue was unchanged. The effect of lactose upon the intestinal mucosa therefore seemed to be qualitatively the same as fasting; the differences were quantitatively greater in fasted, lactose-treated rats (compared to fed controls).

- 7134 ACTIVE TRANSPORT OF D-XYLOSE IN THE ISOLATED SMALL INTESTINE OF THE BULLFROG. (E.) Lassen, U. V. (U. Kentucky Coll. Med., Lexington) and T. Z. Csaky. *J. Gen. Physiol.* 49(5):1029-1041, 1966.

In the presence of sodium as the principal cation in the mucosal medium, the transport rate of D-xylose from the mucosa to the serosa of bullfrog duodenum-ileum preparations was about 5 times greater than the serosa-to-mucosa transport rate, indicating active intestinal transport for D-xylose. If the principal cation on the mucosal side was potassium, the mucosa-to-serosa transport rate was reduced by a factor of 5-6, whereas the serosa-to-mucosa transport was unchanged. This asymmetry was also significantly reduced by addition of a cardioactive steroid (ouabain) to the mucosal and serosal compartments. The structural requirements hitherto considered necessary for active sugar transport in the intestine must be revised, since D-xylose does not meet these criteria.

ABSORPTION

- 7135 AMINO ACID AND SUGAR TRANSPORT IN RABBIT ILEUM. (E.) Schultz, S. G. (Harvard Med. Sch., Boston, Mass.), R. E. Fuisz and P. F. Curran. J. Gen. Physiol. 49(5):849-866, 1966.

In the presence of sodium, L-alanine was rapidly accumulated by rabbit ileum mucosal tissue in vitro; the intracellular conc. exceeded the extracellular conc. by a factor of about 10 after 30 min. of incubation. In the absence of extracellular sodium, however, the final ratio of intracellular:extracellular L-alanine remained about 1.0 and the rate of net uptake was greatly inhibited. Intracellular alanine apparently exists in an unbound, osmotically active form, while accumulation is an active transport process. The accumulation of L-alanine was also inhibited by ouabain. Similar inhibition by ouabain or absence of sodium in the medium was also noted with respect to the uptake of 3-O-methyl-D-glucose.

- 7136 BIOSYNTHESIS OF LIPOPROTEIN BY RAT INTESTINAL MUCOSA. (E.) Hatch, F. T. (Lawrence Radiation Lab., Livermore, Cal.), Y. Aso, L. M. Hagopian and J. J. Rubenstein. J. Biol. Chem. 241(8):1655-1665, 1966.

The "lowest density lipoprotein" isolated from rat intestinal mucosa cells during fat absorption was studied by thin layer chromatography and electrophoresis. The protein moiety was not homogeneous, but seemed to consist of a few species that could be separated electrophoretically. In addition to its affinity for lipids, this protein showed several other unusual characteristics: a predominance of apolar amino acids; resistance to fractionation procedures involving ionic properties; marked solubility in organic solvents; and peculiarities of the peptide map. Peptide maps obtained after proteolytic digestion of the protein moieties of the "lowest density lipoprotein," the residual soluble protein, and lymph chylomicrons, showed a strong though not perfect resemblance.

- 7137 AMINO ACID TRANSPORT BY THE SMALL INTESTINE OF THE RAT. THE EXISTENCE AND SPECIFICITY OF THE TRANSPORT MECHANISM OF IMINO ACIDS AND ITS RELATION TO THE TRANSPORT OF GLYCINE. (E.) Munck, B. G. (U. Copenhagen, Denmark). Biochim. Biophys. Acta 120(1):97-103, 1966.

In everted rat small intestine sacs, a separate transport mechanism for imino acids was demonstrated in several studies. This mechanism was used by glycine, betaine, leucine, alanine, proline, hydroxyproline, and sarcosine. Glycine showed an affinity for both neutral amino acid and imino acid transport mechanisms. The affinities of amino acids for the "imino acid carrier," estimated from their inhibitory effect on sarcosine transport, were ranked into the sequence proline, alanine, betaine, leucine, and glycine (in decreasing order of affinity). It is suggested that the alanine-preferring mechanism ('A-mediation') of neutral amino acids in Ehrlich ascites tumor cells may be a manifestation of an imino acid transport mechanism in these cells.

- 7138 ABSORPTION OF MEDIUM-CHAIN FATTY ACIDS BY THE DOG COLON. (E.) Pihl, B. G. (Tufts U. Sch. Med., Boston, Mass.), D. J. Glotzer and J. F. Patterson. J. Appl. Physiol. 21(3):1059-1062, 1966.

The rate of absorption by an isolated colon loop of the sodium salts of hexanoic, octanoic, and decanoic acids from a recirculated aqueous soln. was essentially the same for all 3 compounds (0.013-0.016 mEq/cm²/hr. in 3 dogs). In 1 experiment with several conc. of sodium octanoate (20, 30, or 40 mg/ml), a conc.-dependent linear increase in the absorption rate was noted. The absorption rate was constant over 2 hr. of continuous perfusion. This rate of absorption of medium-chain fatty acids in the dog colon is about 25% of the rate reported for the human jejunum.

- 7139 DEPENDENCY OF IRON RESORPTION UPON THE BINDING OF IRON BY THE INTESTINE. (Ger.) Forth, W. (U. Saarland, Homburg, Germany) and W. Rummel. Med. Pharmacol. Exp. (Basel) 14(4):384-390, 1966.

In the rat, following intragastric admin. of ferric chloride marked by radio-active iron, a progressive increase of the amount of iron taken up into the body was directly proportional to the decrease of iron which remained bound by the duodenal mucosa, both values reaching a plateau within approx. 24 hr. When the

ABSORPTION

marked ferric chloride was admin. with pyrophosphoric acid, the amount of iron bound by the duodenal mucosa was decreased by two-thirds, while uptake into the body was diminished by the same amount with resorption ended within 12 hr. The authors conclude that the amount of iron bound in the intestinal wall is a primary determining factor for the amount which can be incorporated into the organism as a whole.

- 7140 COMPETITION FOR TRANSPORT BETWEEN METHYLDOPA AND OTHER AMINO ACIDS IN RAT GUT LOOPS. (E.) Young, J. A. (Sydney Hosp., New South Wales, Australia) and K. D. G. Edwards. *Am. J. Physiol.* 210(5):1130-1136, 1966.

In a study of the transport of the L and D isomers of methyl dopa (α -methyl-3,4-dihydroxy-phenylalanine) and their inhibition of natural amino acid transport, use was made of *in situ* loops of rat jejunum. L-Methyl dopa was absorbed very slowly although significantly more than the D isomer. In a latin-square experiment, the effects of L- and D-methyl dopa and mannitol (as a poorly absorbed control) on histidine transport were compared. Mannitol significantly reduced histidine absorption, indicating sensitivity of histidine transport to adverse osmotic gradients. D-Methyl dopa reduced histidine absorption but not significantly more than mannitol. L-Methyl dopa reduced histidine absorption significantly more than mannitol and D-methyl dopa. It was thought that L-methyl dopa inhibited amino acid transport mechanism(s) having specificity for L configurations. Mannitol and L- and D-methyl dopa were all without effect on glucose absorption, suggesting that methyl dopa had no nonspecific effects on intestinal metabolism. Further studies demonstrated inhibition of transport of glutamic acid, glycine, lysine, taurine, and phenylalanine, but not methionine or proline by L-methyl dopa, suggesting that it had a more general inhibitory action on amino acid transport than competitive inhibition of one transport mechanism. Incidental evidence suggested that the amino compound, taurine, was absorbed by a process other than simple diffusion.

- 7141 INTESTINAL BILE SALT TRANSPORT: STRUCTURE-ACTIVITY RELATIONSHIPS AND OTHER PROPERTIES. (E.) Lack, L. (Duke U. Med. Ctr., Durham, N. C.) and I. M. Wiener. *Am. J. Physiol.* 210(5):1142-1152, 1966.

Guinea pig small intestine everted sacs (technic of Wilson and Wiseman) were used in all studies. The intestine actively transports conjugated derivatives of cholic acid having 2 of 3 hydroxyl groups or ketonic groups. The trihydroxy compounds are better transported than are the dihydroxy compounds. Among the dihydroxy compounds there was little difference in transport. The series of dihydroxy compounds included 2 unnatural compounds (7α , 12α and 3-chloro, 7α , 12α). The ability to be transported was not greatly influenced by changes in the conjugating moiety unless this involved changing the number of potential negative charges. A positively charged derivative was not transported. All active transport was limited to the ileum. The transport of a given bile salt is depressed in the presence of a second. This is consistent with the operation of a single transport system; however, part of the mutual inhibition observed is attributable to a general effect of bile salts on mucosal function. Dihydroxy bile salts are more potent inhibitors than trihydroxy bile salts while the triketo derivative is the least potent.

- 7142 HYDROXOCOBALAMIN. VI. COMPARISON OF INTESTINAL ABSORPTION IN MAN OF LARGE DOSES OF HYDROXOCOBALAMIN AND CYANOCOBALAMIN. (E.) Weisberg, H. (New York Med. Coll., N. Y.) and G. B. J. Glass. *Proc. Soc. Exp. Biol. Med.* 122(1):25-28, 1966.

In 3 pairs of normal subjects, Co⁵⁷-labeled cyanocobalamin and Co⁶⁰-labeled hydroxocobalamin were admin. simultaneously in oral doses of 100, 500 and 1,000 μ g and the ratio of the 2 isotopes in whole stool specimens was compared with that in the admin. dose. No significant differences were found between the ratios admin. and excreted at each dosage level. In 11 subjects intestinal adsorption was quantitated by a modification of the double label hepatic uptake test in which the hepatic uptake of orally admin. cyanocobalamin-Co⁵⁷ and hydroxocobalamin-Co⁵⁷ was given simultaneously with the first oral dose. At oral doses of 100, 500, and 1,000 μ g, mean hydroxocobalamin and cyanocobalamin absorption was not significantly different.

ABSORPTION

- 7143 ABSORPTION OF ^{14}C TRIOLEIN IN THE BILE FISTULA RAT. (E.) Cesano, L. (Royal Free Hosp., London) and A. M. Dawson. Proc. Soc. Exp. Biol. Med. 122(1):96-99, 1966.
- Six male, adult albino rats (200-300 g) were provided with a bile fistula; 7 rats were subjected to a sham operation. The day after operation and 4 hr. before sacrifice, each rat was given 0.2 ml (1 μC) of ^{14}C -triolein by gavage. In bile fistula animals there was a diminished absorption and decreased lipolysis of the triolein. Analysis of small intestine mucosal lipid showed a greater proportion of radioactivity in the free fatty acids and lower glycerides of the bile fistula animals than of controls. The distribution of radioactivity in different parts of the stomach and intestine did not differ between normal and bile fistula rats either with respect to intestinal contents or the mucosa. In both groups the mucosal radioactivity was present predominantly in the distal two-thirds of the small intestine; in both groups most luminal radioactivity was in the distal third.
- 7144 ACYL GROUP EXCHANGE IN THE INTESTINAL LUMEN DURING FAT DIGESTION. (E.) Reiser, R. (Texas A & M U., College Station) and Hwei Choung Fu. Biochim. Biophys. Acta 116(3):563-569, 1966.
- Rats were admin. 1- H^3 -glycerol-1- ^{14}C -trioleate together with unlabeled oleic acid or triglyceride, or treated with mixtures of ^{14}C -labeled oleic and palmitic acids together with unlabeled cottonseed oil. Equations were developed for calculating the percentages of acyl groups exchanged under various conditions in the intestinal lumen. These studies showed that less than 1% of the acyl groups of triglycerides are exchanged with free fatty acid; 95% of these acyl groups are in positions 1 and 3. About 2.5% of saturated and 10% of unsaturated acyl groups from triglycerides are exchanged with the oleic acid from triolein during digestion and absorption. The unhydrolyzed portions of the digested triglycerides are absorbed as monoglycerides, while the triglycerides are reconstituted in the intestinal mucosa.
- 7145 THE ROLE OF MACROPHAGES IN IRON METABOLISM AT THE LEVEL OF THE DUODENO-JEJUNAL MUCOSA. (Sp.) Astaldi, G. (City Hosp., Tortona, Italy) and G. Meardi. Sangre (Barc.) 11(1):3-31, 1966.
- Histochemical studies (Perls' test) were conducted to determine the iron content of macrophages of the lamina propria of duodenojejunal mucosa specimens obtained by peroral biopsy. In 20 normal subjects fasted for more than 18 hr., no positive-staining granules were found in the epithelium or lamina propria of the duodenal villi, while the lamina propria of the first portion of the jejunum contained numerous siderocytes with hemosiderin-containing granules. In 10 patients with post-transfusion hemosiderosis, the number of siderocytes (30.8-62.4%) as well as the size and intensity of staining of the hemosiderin granules were markedly increased with respect to the preceding group. In a patient with sideropenic achrestic anemia treated with iron saccharate (40 mg/day i.v.; total 1,720 mg), marked siderocytosis was observed in the epithelium and lamina propria of the duodenum; siderocytes were similar to those observed in the group with hemosiderosis, but distributed along the axis as well as at the apex of the villi. In a patient with idiopathic hemochromatosis, hemosiderin granules were found mostly in the epithelial cells in the apical portion of the duodenal villi and the number of positive-staining cells was less than in the preceding patient. Findings indicate that these intestinal macrophages play an important role in the storage and elimination of endogenous and exogenous iron.
- 7146 INCREASING DISSOLUTION RATES AND GASTROINTESTINAL ABSORPTION OF DRUGS VIA SOLID SOLUTIONS AND EUTECTIC MIXTURES. II. EXPERIMENTAL EVALUATION OF A EUTECTIC MIXTURE: UREA--ACETAMINOPHEN SYSTEM. (E.) Goldberg, A. H. (U. Michigan, Ann Arbor), M. Gibaldi and J. L. Kanig. J. Pharm. Sci. 55(5):482-487, 1966.
- The dissolution rate of a simple eutectic mixture was compared to the dissolution rate of the drug alone. The binary system of acetaminophen and urea was found to be a simple eutectic mixture with negligible formation of solid soln. Solubility studies indicated that the solubility of acetaminophen was significantly increased

ABSORPTION

by urea. Dissolution rate studies were conducted with acetaminophen alone and in fused and physical mixtures with urea. Findings indicate that under the conditions of the experiment the dissolution process adheres to a mixed mathematical model, i.e., intermediate to a planar surface dissolution model and a particulate dissolution model. In all cases the presence of urea enhanced the dissolution rate of acetaminophen by virtue of a microenvironmental solubilization. Reduction of the particle size of acetaminophen by eutectic formation with urea failed to increase the dissolution rate of the drug. The fused mixture of the eutectic mixture gave similar, but prolonged enhancement of the dissolution rate as compared to the physically mixed sample.

- 7147 INCREASING DISSOLUTION RATES AND GASTROINTESTINAL ABSORPTION OF DRUGS VIA SOLID SOLUTIONS AND EUTECTIC MIXTURES. III. EXPERIMENTAL EVALUATION OF GRISEOFULVIN--SUCCINIC ACID SOLID SOLUTION. (E.) Goldberg, A. H. (U. Michigan, Ann Arbor), M. Gibaldi and J. L. Kanig. J. Pharm. Sci. 55(5): 487-492, 1966.

The role of solid soln. in increasing dissolution rates was evaluated experimentally. The phase diagram for the binary system griseofulvin-succinic acid revealed an eutectic mixture with considerable solid solubility of griseofulvin in succinic acid. Dissolution rates obtained by the tape and oscillating vial methods showed that at 3 min. the ratio of griseofulvin solid soln. to that of the control was almost 7, indicating that the initial rate of dissolution of griseofulvin from a solid soln. containing 20% griseofulvin is approx. 7 times greater than griseofulvin alone. The increased dissolution rate of the micronized form as compared to the crystalline form can be related to only one factor: decreased particle size and increased surface area. Photomicrographs of particles before and after the dissolution study were made possible by the tape method.

- 7148 RADIO-IRON ABSORPTION IN THE RAT AFTER PHENYL HYDRAZINE INDUCED ANAEMIA. (E.) Thompson, J. H. (U. California Sch. Med., Los Angeles). Irish J. Med. Sci. 6(484):127-132, 1966.

In rats admin. phenylhydrazine (50 or 100 mg/kg i.p., single dose), hemoglobin level fell markedly within 30 min. but returned to normal by 20 days, with a second decrease thereafter. The transient increase in hemoglobin levels may have resulted from emptying of splanchnic and bone marrow reserves; this hypothesis was supported by the slight lag period seen at the smaller dose of phenylhydrazine. Absorption of Fe^{59} reached max. values 4 days after the induction of hemolysis; iron absorption was 4-7 times higher than control levels 6 wk. after treatment. Both effects of phenylhydrazine were dose-dependent. Since the onset of iron absorption was no earlier at the higher dose of phenylhydrazine, it is concluded that the iron content of the intestinal mucosal cells is not of prime importance in controlling iron absorption.

- 7149 THE EFFECT OF GENERAL AND LOCAL INTESTINAL HYPOTHERMIA ON THE PRODUCTION AND ABSORPTION OF AMMONIA. (E.) Barker, C. F. (U. Pennsylvania Sch. Med. Philadelphia) and G. W. Peskin. Surgery 59(6):1092-1098, 1966.

In anesthetized dogs, general hypothermia decreased the ammonia levels of the inferior mesenteric vein temporarily, in a self-reversing action; had no significant effect on portal venous, gastric venous or femoral arterial levels. During colonic hypothermia, inferior mesenteric venous levels were doubled initially; stabilized at approx. 150% the original values. Portal venous and femoral arterial levels also doubled, but more slowly. During gastric hypothermia, gastric venous ammonia levels tripled; portal venous levels increased by approx. 63%; femoral arterial levels showed no significant change. When nitrogen in the form of urea was instilled into the stomach (to simulate digested blood), there was a prompt rise of portal venous and inferior mesenteric venous ammonia levels. General hypothermia failed to inhibit either rise significantly. Colonic hypothermia inhibited the extent of the portal venous increase (only) and delayed its appearance slightly. However, both general and colonic hypothermia increased femoral arterial levels, by approx. 10 and 2 times, resp. When urea was instilled into the stomach, general hypothermia

RESORPTION

sharply increased the extent of the almost-immediate rise of gastric venous and portal venous levels. Those of the femoral artery, essentially unchanged by the instillation of urea alone, increased approx. 3 times during general hypothermia. Gastric hypothermia dampened the degree of the gastric venous rise (only) but femoral arterial levels rose by approx. 670% during the first 5 hr. It is concluded that either general hypothermia nor localized gastrointestinal hypothermia shows promise of usefulness in the treatment of ammonia intoxication in the human.

- 150 CALCIUM AND POTASSIUM UPTAKE FROM SODIUM FREE MEDIA BY FROG STOMACH MUSCLE. (E.) Fariduddin, K. M. (Indiana U. Sch. Med., Indianapolis) and W. McD. Armstrong. Proc. Soc. Exp. Biol. Med. 121(4):1280-1283, 1966.

Inhibition of potassium uptake observed in isolated frog stomach muscles when sodium was replaced by lithium in the bathing fluid did not seem to be due to the increased amounts of calcium in the muscle or the subsequent metabolic changes caused by this increased calcium. This conclusion was drawn from the fact that when lithium replaces sodium in a bathing fluid containing 106 mEq Na⁺, 10 mEq K⁺, and 1.8 mEq Ca⁺⁺/1000 ml, the potassium accumulation in frog stomach muscle (previously immersed overnight at 5°C in a sodium-free soln. containing 110 mEq Li⁺, 6 mEq K⁺ and 1.8 mEq Ca⁺⁺/1000 ml) is limited; however, the addition or removal of Ca⁺⁺ from this lithium soln. did not alter the K⁺ content of the muscle.

- 151 VITAMIN D₃-INDUCED CALCIUM-BINDING PROTEIN IN CHICK INTESTINAL MUCOSA. (E.) Wasserman, R. H. (New York State Vet. Coll., Ithaca) and A. N. Taylor. Science 152(3723):791-793, 1966.

White Leghorn cockerels with severe rickets developing after 4-5 wk. of a rachitogenic diet were admin. vitamin D₃ (500 I.U., p.o.) 72 hr. prior to sacrifice and removal of the duodenum. The supernatant of the duodenal mucosal homogenate from these chicks demonstrated increased calcium binding by causing a slower diffusion of Ca⁴⁵ across a Visking cellophane dialyzing membrane, and by lessening the Ca⁴⁵ sequestered by an ion exchange resin. The binding rate of the rachitic supernatant was unaltered by added Ca⁴⁰; in the group which received vitamin D₃, the supernatant behaved as a binding substance with a certain saturation point. When 2.5 mg of crystalline trypsin was incubated with the latter supernatant, the enhanced binding activity was destroyed within 4 hr. The duodenal supernatant from the rachitic group was unaffected by trypsin. The absorption rate of Ca⁴⁷ by the ligated duodenum of rachitic chicks treated with vitamin D₃ i.m. showed a similar time pattern as the conc. of the supernatant binding factor in the former group, implicating this factor as the mechanism for vitamin D₃-enhanced calcium absorption.

- 152 TRANSMURAL POTENTIALS ACROSS THE SMALL AND LARGE INTESTINE OF THE BULLFROG, Rana catesbeiana. (E.) Levin, R. J. (U. Iowa, Iowa City). Proc. Soc. Exp. Biol. Med. 121(4):1033-1038, 1966.

The electrical potential difference across the small and large intestine of the bullfrog in vitro was measurable in the presence of sugars and amino acids to the extent that it may serve in the investigation of solute transfer or active transport. Since the potential difference was maintained after 5 hr. of incubation or after 30 min. under anoxic conditions, this assay proved to be more stable than ones using mammalian intestine; it had the further advantage of incubation at room temperature. Addition of glucose (5.6 mM) to everted bull-frog small intestine segments in sulfate saline caused a rapid rise in potential difference, which was immediately depressed by phlorizin. This same pattern occurred with sorbose, xylose, sucrose, mannitol, urea, ascorbic acid, and sodium acetate. A similarly increased potential difference occurred after the addition of 5.6 mM glycine, but this was not affected by phlorizin. All additions were made to the mucosal fluid as the potential difference was serosa (positive) to mucosa. The potential difference of the large intestine did not increase with glycine or glucose, but was markedly depressed by anoxia or dinitrophenol, indicating that the differing electrical characteristics of the small intestine are due to an active transfer mechanism.

- 153 RELATIONSHIP BETWEEN RESORPTION AND BLOOD CIRCULATION IN SMALL INTESTINE. (Ger.) (Rev.) Varró, V. (U. Szeged, Hungary). Internist (Berlin) 7(5):250-255, 1966.

SECRETION

- 7164 ACTION OF ANTIDIURETIC HORMONE ON GASTRIC SECRETION. (E.) Schapiro, H. (U. Tennessee Med. Units, Memphis), E. H. Storer and L. G. Britt. Arch. Surg. (Chicago) 92(5):699-703, 1966.

A linear reduction in the gastric secretion vol. in Heidenhain pouch dogs occurred after graded dosage of the following: 5-50 mU/kg of antidiuretic hormone; 0.75-5.0 g/kg of glucose (i.v. or intracarotid inj.); and 0.25-1.0 g/kg of NaCl i.v. In all these cases, the free acid conc. remained constant. Gastric secretory inhibition was not obtained with 50 or 100 mU/kg of oxytocin i.v., or with 100 ml of 0.9% NaCl i.v., and was essentially absent with 50 mU/kg of NaCl-inactivated antidiuretic hormone. Blood flow in the celiac artery was unaltered by 20-50 mU/kg of antidiuretic hormone. Generally, gastric secretion was maintained for testing by continuous histamine inj.

- 7165 EFFECTS OF A GASTRIN-LIKE PENTAPEPTIDE (I.C.I. 50,123) ON STOMACH AND PANCREAS. (E.) Wormsley, K. G. (Royal Infirm., Manchester, England), M. P. Mahoney and M. Ng. Lancet 1(7445):993-996, 1966.

A peak stimulation of gastric output was obtainable (generally within 30 min.) in 7 of 29 volunteers who were admin. a gastrin-like pentapeptide (I.C.I. 50,123; 0.01-0.1 µg/kg/min. by constant i.v. infusion). Upon termination of the infusion, acid output returned to basal levels within 15 min. In cases where the pancreas was primed by secretin (1.0-6.0 U/kg/hr., constant i.v. infusion), this pentapeptide stimulated bicarbonate and enzyme output of the pancreas, but at somewhat higher doses. These secretions usually peaked within 20 min. Along with these increases, there was a greater influx of bile and sodium chloride into the duodenum. Abdominal cramps, nausea and vomiting occurred in 3 of 16 patients who received 0.1 µg of the peptide, and hypotension arose in 3 of 6 patients who were admin. 5 µg/kg s.c. A gastric acid peak response to ametazole (constant i.v. infusion; 0.5-4.0 mg/kg/hr.) was far more difficult to obtain due to complaints of discomfort, indicating that this readily available pentapeptide would seem to be more useful in obtaining a gastric function parameter.

- 7166 INCREASED ACID SECRETION FROM HEIDENHAIN POUCHES BY SHUNTING COLONIC VENOUS BLOOD AROUND THE LIVER. (E.) Clarke, J. S. (U. New Mexico Sch. Med., Albuquerque), I. Miller and P. K. McKissock. Arch. Surg. (Chicago) 92(5):653-656, 1966.

Acid secretion in Heidenhain pouch dogs increased after colonic venous blood was diverted around the liver via an inferior mesenteric vein to vena cava shunt. A similar marked increase in acid secretion occurred following a portacaval transposition made cephalad to the previous shunt, which redirected the colon venous blood to the liver and shunted the portal blood from the stomach, spleen, pancreas, duodenum, and small intestine. Previous experiments had demonstrated that all but the last organ showed no augmented secretion. The authors propose that a secretagogue (possibly histamine) which is normally removed by the liver is released in roughly equal amounts into the portal blood from both the small intestine and colon.

- 7167 GASTRIC SECRETORY PATTERNS BEFORE AND AFTER VAGOTOMY. (E.) Bitsch, V. (Bispebjerg Hosp., Copenhagen, Denmark), V. Faber, P. M. Christiansen and P. Rødbro. Lancet 1(7450):1288-1291, 1966.

Histamine- and insulin-stimulated gastric acid, pepsin, and intrinsic factor secretion was studied in 10 men with duodenal ulcers before and after truncal vagotomy with Heinecke-Mikulicz pyloroplasty (9 cases) or gastrojejunostomy (1 case). A temporary gastrostomy was made in all patients. The secretory patterns of vol. and acidity showed a sustained response to stimulation, while the intrinsic factor and pepsin secretion tests showed a "wash-out" response of short duration. These secretory patterns were of the same form pre- and postoperatively after histamine stimulation, although the postoperative responses were smaller. After insulin stimulation, however, the secretion patterns were much alike for all components studied, with an initial depression followed by a return to basal values. Vagotomy had a significant influence upon all components studied.

SECRETION

- 7168 GASTRIC ACID SECRETION AND Parietal Cell Mass in the Stomach of a Newborn Infant. (E.) Polacek, M. A. (Marquette U. Sch. Med., Milwaukee, Wis.) and E. H. Ellison. Am. J. Surg. 111(6):777-781, 1966.

Total stomach specimens were obtained within 4 hr. of autopsy from 4 newborn infants (ages 2-16 hr.). In these specimens the parietal cell mass was 2-3 times greater than that of the normal adult, and was great enough to induce (by gastric acid secretion) peptic ulcers. In the newborn, the parietal cell mass was highest in the corpus (max. in the midportion), decreased in density in the incisura and cardia and was absent in the prepyloric-antral region. No parietal cell mitosis appeared in these newborns' stomachs. The relationship between these findings and maternal hyperacidity in the last trimester of pregnancy is discussed.

- 7169 EFFECT OF SEVENTY-FIVE PER CENT DISTAL SMALL BOWEL RESECTION ON GASTRIC SECRETION. (E.) Reul, G. J. (Marquette U. Sch. Med., Milwaukee, Wis.) and E. H. Ellison. Am. J. Surg. 111(6):772-776, 1966.

Heidenhain fundic pouches were constructed in 6 adult female dogs and control samples were taken from them 16-47 days prior to a 75% distal small intestine resection (from the ligament of Treitz to about 3 inches proximal to the ileocecal valve) with jejunoileal anastomosis. An immediate gastric hypersecretory state was induced by this operation, resulting in a prolonged basal hypersecretion and a mean increase of 322% in the 24-hr. gastric secretion (vol. and total acid output). In these animals, the response to max. histamine stimulation did not change, delayed acid production followed meal ingestion, and av. wt. loss was only 7%. The acid hypersecretion did not arise from anemia, electrolyte imbalance, quantitative changes of food intake, or morphological liver or pancreas changes. However, the number of gastric mucosal parietal cells had markedly increased. At autopsy the intestinal wall had thickened and was occasionally dilated.

- 7170 A PRACTICAL CONSIDERATION IN THE CONSTRUCTION OF GASTRIC POUCHES. (E.) Cobbin, O. (U. Minnesota Sch. Med., Minneapolis), W. P. Ritchie, Jr. and J. P. Delaney. Surgery 59(6):1099-1100, 1966.

A new method is described for introducing a cannula into a gastric pouch, for drainage. It avoids the disadvantage of placing undue stress on the newly-created suture line and reduces the size of the incision in the wall of the pouch to the size of the barrel of the cannula.

- 7171 STUDIES ON THE VISCOSITY OF GASTRIC JUICE. (Rum.) Zălaru, M. C. (Stud. Polyclin. Hosp., Bucharest, Rumania). Med. Intern. (Bucur.) 18(1):89-98, 1966.

Viscosity was determined with the original Ubbelohde viscosimeter (100 tests) and with a newly devised modified version (40 tests) designed to utilize smaller samples (3-4 ml) of gastric juice. With both devices, the viscosity of the gastric juice proved to vary as a function of its acidity, according to an exponential curve described by the equation $y = 60e^{-0.002x}$. Scattering of the results, in terms of the mean values and weighted error of the mean ($M \pm 3 \text{ e.m.}$), in subjects with normo- and hypoacidity indicated that determination of viscosity is a valuable auxiliary research tool, e.g., for identifying cases in which there is an increase in the concentration of colloids (probably mucins for the most part) in the gastric juice. The further observation that viscosity decreased as temperature increased is evidence for the probable linear structure of the macromolecules of the gastric juice.

- 7172 CORRELATION OF PEPSIN CONCENTRATION IN THE GASTRIC JUICE AND OF SERUM AND URINARY PEPSINOGEN IN ULCER DISEASE. (Rum.) Schwartz, M. (Inst. Med. Physiol., Cluj, Rumania), S. Popescu, C. Calu, D. Grigoras, A. Goia and O. Fodor. Med. Intern. (Bucur.) 18(2):167-176, 1966.

Pepsin secretion and pepsinogen levels (mg pepsin/ml gastric juice or urine) were determined in 15 normal subjects and in 70 patients with gastric and/or duodenal ulcer, under basal conditions and after stimulation with 0.04 mg/kg histamine. Under basal conditions, av. pepsin conc. was about the same in patients with either gastric or duodenal ulcer: 26.6 ± 12.2 and 27.1 ± 6.1 , resp., as compared with

SECRETION

4.9 $\pm$ 10.4 in controls. It was highest in patients with pyloric stenosis (av. 13.2 $\pm$ 19.1), and lowest in those with gastroduodenal ulcer (av. 12.7 $\pm$ 10.3) and those who had undergone gastric resection (av. 8.4 $\pm$ 4.2). After histamine stimulation, substantial increases were noted in all groups; these were greatest in patients with gastroduodenal and duodenal ulcers, and especially in cases complicated by pyloric stenosis (av. 45.3 $\pm$ 14.3, 50.7 $\pm$ 17.3, and 61.1 $\pm$ 24.1, resp.). HCl conc. was not consistently correlated with pepsin conc.; patients with gastric ulcer had the highest pepsin secretion in relation to HCl secretion. Pepsin output increased abruptly after histamine stimulation and remained high for 60-90 min., especially in the presence of duodenal ulcer or ulcer complicated by pyloric stenosis. Urinary excretion of pepsin was highest in the duodenal ulcer group (99 mg/24 hr.), although the values were within normal limits in 60% of this group, as well as in the others. After histamine, urinary pepsinogen usually increased 10-20%, but decreases were also observed. Serum pepsinogen levels were comparable in all groups under basal conditions, and were relatively unaffected by histamine administration. It may therefore be an index of cell mass, rather than a reflection of their functional activity.

- 173 THE INFLUENCE OF Mg⁺⁺ IONS ON THE VISCOSITY OF HUMAN SALIVA AND THE ACTIVATION OF MUCOLYTIC ENZYMES. (Ger.) Schilli, W. (U. Freiburg i. Br., Germany), G. Ochs and J. Eschler. Zschr. Laryng. Rhinol. Otol. 45(2): 110-113, 1966.

Among 5 subjects in whom the technic was tested, the viscosity of both normally and abnormally viscous saliva secreted from the parotid gland was somewhat decreased during and after i.v. inj. of a soln. of magnesium salts, while that secreted from the submaxillary gland was decreased markedly. Chromatographic study confirmed that this decrease was accompanied by release of free glucose and galactose, apparently separated from macromolecular glucuronic acids by Mg⁺⁺-activated mucolytic enzymes. In an unspecified number of patients with inflammations of the salivary gland(s), the same treatment decreased discomfort considerably.

- 174 MAXIMAL ACID OUTPUT IN NORMAL NEWBORN INFANTS FOLLOWING HISTALOG STIMULATION. (Sp.) Espejo Romero, H. (Nat. U. San Marcos, Lima, Peru), N. Yalan Igreda, A. Chahud Isee, C. Livia Becerra and H. Lara Cubas. Arq. Gastro-ent. 2(4):163-172, 1966.

Max. gastric secretion after Histalog stimulation (1.7 mg/kg s.c.) was studied in 10 normal newborn infants 3-37 hr. after birth. Acid output 30-90 min. after stimulation was not notably higher than the basal acid output. Total basal vol. of gastric secretion decreased progressively from 15-60 min.; after stimulation, the vol. of gastric secretion remained constant while the acid output increased progressively. The av. values of acid secretion were: 0.174 mEq basal; 0.146 mEq 1 hr. after stimulation; 0.168 mEq 30-90 min. after stimulation. Achlorhydria was not observed in any of the subjects. Results indicate that gastric secretion is much less in the newborn than in adults in proportion to body wt., most likely because of the reduced number of secretory cells in the stomach of the former.

- 175 THE EFFECT OF PREDNISOLONE ON GASTRIC MUCOSAL HISTOLOGY, GASTRIC SECRETION, AND VITAMIN B₁₂ ABSORPTION IN PATIENTS WITH PERNICIOUS ANEMIA. (E.) Jeffries, G. H. (Cornell U. Coll. Med., New York, N. Y.), J. E. Todd and M. H. Sleisenger. J. Clin. Invest. 45(5):803-812, 1966.

Control studies of 6 patients with pernicious anemia, 1 with latent pernicious anemia and 1 with atrophic gastritis without pernicious anemia revealed that all of the patients were achlorhydric following Betazole stimulation; only 1 of 8 had intrinsic factor in the gastric juice; the urinary excretion of B₁₂ (Schilling test) was low in 7 of 8; and all patients had atrophic gastric mucosa. Prednisolone, 10-40 mg/day i.o., was continued for 2-8 mo. and 6 of 8 patients received 100 μ g B₁₂ i.m. monthly. During the steroid therapy, 3 patients secreted both acid (after Betazole) and intrinsic factor while intrinsic factor alone was found in 2 patients. There was an increase in B₁₂ absorption as shown by an increase in the urinary excretion of B₁₂ in 5 of 8 patients. The control B₁₂ level was normal in the patient with atrophic gastritis and remained normal during therapy. During the prednisolone treatment,

SECRETION

parietal cells were identified in gastric specimens from 5 of 8 patients but there was no reduction of parietal cell antibodies in the sera of 7 of 8. The study indicated that the atrophic gastric mucosa in patients with pernicious anemia may retain its potential to regenerate parietal cells.

- 7176 EFFECT OF INCREASING DOSES OF SECRETIN ON THE HUMAN PANCREAS. MAXIMUM SECRETION CAPACITY. (Fr.) Sarles, H. (Sainte-Marguerite Hosp., Marseille France), G. Prezlin, C. Souville and C. Figarella. Rev. Franc. Etud. Clin. Biol. 11(3):294-298, 1966.

The effect on pancreatic secretion of progressively increasing doses of secretin was studied in 3 patients after single inj. of Vitrum secretin (0.5-64 U/kg) or of verified secretin (2-20 U/kg), and in 16 patients (age 25-58 yr.) after continuous perfusion of 1-25 U/kg over a 6-8-hr. period. Patients were without pancreatic disease and were selected for their low body wt. Max. bicarbonate output measured at 5-min. intervals for 150 min. after inj. was used as an indication of pancreatic activity. Max. secretion occurred with minimum doses ranging from 16-32 U/kg with Vitrum secretin and from 16-20 U/kg with verified secretin. In perfused patients, max. bicarbonate output was assessed for 30 min. after obtaining a plateau in bicarbonate and total output curves upon maintenance of continuous perfusion for at least 2 hr. In these patients, max. secretory response occurred between the doses of 15-25 U/kg/hr.

- 7177 EFFECTS OF SERUM URIC ACID AND PAROTID FLOW RATE ON CONCENTRATION AND SECRETION RATE OF URIC ACID IN PAROTID FLUID. (E.) Shannon, I. L. (U.S.A.F. Sch. Aerospace Med., Brooks Air Force Base, Texas). Proc. Soc. Exp. Biol. Med. 122(1):227-230, 1966.

Uric acid conc. was determined in the serum and parotid fluid (without exogenous stimulation) of 508 healthy males between 17 and 22 yr. old. Uric acid content was measured on the Technicon Auto-Analyzer by a sodium cyanide-phosphotungstic acid procedure in which the blue color of the reaction is read at 660 m μ in a 15 mm light path. The mean conc. of uric acid was 9.52 mg/100 ml for parotid fluid and 5.70 mg/100 ml in serum; significant correlation ($r = .398$) was found between the 2 values. Parotid flow rate was positively correlated ($P < .001$) with the secretion rate for uric acid ($r = .796$) but negatively correlated ($P < .001$) with uric acid conc. ($r = -.524$). It is believed that the transport of uric acid can be explained by reabsorption (probably in the proximal portion of the duct system) which brings it to a relatively common conc. by a total or limited capacity process, and the uric acid is secreted into the saliva by cells of other ductal segments.

- 7178 REPRODUCIBILITY OF THE SECRETIN TEST IN HEALTHY SUBJECTS. (Ger.) Gülzow M. (U. Rostock, Germany), W. Teichmann and R. Arendt. Acta Biol. Med. German. 15(4):500-512, 1965.

Pancreatic function tests were performed before and 10-80 min. after the admin. of secretin (75 U i.v.) on each of 3 occasions at 6-9-day intervals in 4 normal subjects. The av. variability coefficient of results of tests of fluid vol. and bicarbonate and chloride excretion was 33%; marked individual variations were noted, which made determination of normal values very difficult. Variance analysis of the results indicated that both the secretion vol. 20 and 40 min. after secretin admin. and the bicarbonate conc. after 10 and 40 min., were significantly higher than both the preliminary results and the results obtained after 60 and 80 min. Bicarbonate conc. reached max. values 20 min. after secretin admin., but very marked individual differences were noted. Chloride conc. was significantly lower after 10-40 min. than during the previous period or after 60-80 min. The correlation coefficient between bicarbonate and chloride conc. was greater (-0.820) than that between secretion vol. and chloride conc. (-0.556).

- 7179 STUDIES ON GASTRIC JUICE SECRETION OF DIABETIC PATIENTS. (Jap.) Fujimoto T. (Sapporo Coll. Med., Japan). Sapporo Igaku Zasshi (Sapporo Med. J.) 27(1-2):65-80, 1965.

Gastric secretion vol. and acidity were significantly lower in diabetic patients than in normal subjects of the same age groups; this difference was especially

SECRETION

marked in patients over 30. A decrease in gastric secretory function in the diabetic patients was also associated with elevated fasting blood glucose levels, inadequate therapeutic control, and low insulin sensitivity indices. Nocturnal basal gastric juice secretion was also lower in diabetics than in normal controls; there was a good correlation between this parameter and the insulin sensitivity index. Gastric juice from diabetic patients usually contained below normal conc. of glandular mucoprotein and above normal levels of dissolved mucoproteose, protein-bound hexose, hexosamine, and sialic acid. There was a significant correlation between blood glucose levels and the levels of free reducing sugars in the visible mucus (which showed high *in vitro* glucose adsorption) and soluble mucin. The conc. of serum proteins in the gastric juice was also elevated in diabetes.

- 180 EFFECT OF ETHIONINE INGESTION ON BILIARY SECRETION AND BILE TREE CAPACITY IN RATS. (E.) Barber-Riley, G. (U. Malaya, Kuala Lumpur, Malaysia). *Experientia* 22(4):233-234, 1966.

After 40 days of ethionine feeding (50 mg/day), the mean biliary flow rate in rats increased by 38% (mean 4.5 and 3.4 ml/hr./kg, resp.) and the mean max. intrabiliary pressure following constriction of the bile duct decreased by 24% (12.6 and 16.5 mm water, resp.). Mean max. dye conc. in ethionine-treated rats, measured with sulfobromophthalein or Blue EG, were 23.2 ± 8.1 and 25.2 ± 10.1 mg/100 ml, resp., compared to 39.2 ± 8.7 and 42 ± 9.8 mg/100 ml, resp., in untreated controls. The mean dye capacity of the liver increased by 34% (using sulfobromophthalein) or 37% (using Blue EG) in rats with undistended bile ducts; in animals with distended bile ducts, mean dye capacity increased by 40% and 44%, resp. Bile clearance from the distended biliary tree was exponential with time in both ethionine-treated and control rats. There was no significant change in liver wt. after ethionine treatment, but histological examination of the livers of treated animals showed proliferation of the bile ductules, which was limited to areas surrounding the smaller veins of the portal tracts.

- 181 THE MECHANISM OF THE INHIBITION OF GASTRIC SECRETION PRODUCED BY ESOPHAGEAL LIGATION IN THE PYLORUS-LIGATED RAT. (E.) Brodie, D. A. (Merck Inst. Ther. Res., West Point, Pa.) and P. G. Knapp. *Gastroenterology* 50(6):787-795, 1966.

In pylorus-ligated rats (ligation for 18 hr.), esophageal ligation significantly inhibited the vol., titratable acidity, and titratable acid output; the ulcer incidence was reduced from 90% to 10%, and there were no deaths or perforated ulcers compared to 80% perforations and a 70% mortality rate with pylorus ligation only). After pylorus and esophageal ligation, admin. of saliva or phosphate buffer increased titratable acidity, but not the secretion vol., to the level seen after pylorus ligation alone. Removal of the salivary glands did not affect gastric secretion, but gastric secretion was stimulated by histamine, carbachol, insulin, and 2-deoxyglucose. After vagectomy, carbachol stimulated gastric secretion but insulin and 2-deoxyglucose did not. It is concluded that rat saliva contains no specific gastric stimulant, and that esophageal ligation inhibits gastric secretion by inhibiting the central vagal activity.

- 182 HISTIDINE INDUCED SECRETION IN THE PYLORIC LIGATED RAT STOMACH. (E.) Rasanen, T. (U. Helsinki, Finland). *Acta Physiol. Scand.* 66(4):481-483, 1966.

In the 1 hr. pylorus-ligated rat stomach, treatment with histidine resulted in a significantly greater secretion vol. and acidity (av. vol. 7.06 ml, av. pH 2.01) than did histamine (av. vol. 4.00 ml, av. pH 3.26). Pretreatment with dexamethasone, which resulted in the almost total disappearance of the granules from the mucosal mast cells, increased the pH of the gastric juice after histidine and histamine admin. (av. pH 3.69 and 3.91, resp.), but abolished the difference between these agents with respect to gastric secretion vol. (av. 6.07 and 5.10 ml, resp.). It is suggested that the gastric parenchyma is stimulated initially by histamine formed from histidine and stored in the mucosal mast cells.

- 183 POTENTIATION OF ACID SHAM FEEDING RESPONSE IN PAVLOV POUCH DOGS BY HISTAMINE AND BY MESENTERIC-CAVAL VEIN ANASTOMOSIS. (E.) Olbe, L.

SECRETION

(Karolinska Inst., Stockholm, Sweden). Acta Physiol. Scand. 66(4):473-480, 1966.

Resection of the main sources of endogenous gastrin (antrum, duodenal bulb, and a distal cm of the acid-producing mucosa) nearly abolished the acid responses to sham feeding in dogs with Pavlov or Heidenhain pouches. Admin. of subthreshold doses of histamine greatly increased the sham feeding responses (by a factor of 5-43 in 5 dogs, depending on the dosage); end-to-side mesenteric-caval vein anastomosis resulted in a 7-20-fold increase in the acid response to sham feeding in the same animals. The dose-response relationship for histamine was unchanged by mesenteric caval anastomosis. Portacaval transposition increased the acid responses to insulin in 3 Pavlov pouch dogs (the increase was significant in 2 animals); these responses were not affected by subsequent antral resection. Two Heidenhain pouch dogs did not respond to insulin either before or after portacaval transposition. The sham feeding responses in 2 Pavlov pouch dogs rose significantly after portacaval transposition; prior or subsequent antral resection did not change this response. In a Heidenhain pouch dog with portacaval transposition, no increase in fasting acid secretion was seen after sham feeding. It is concluded that potentiation of the direct vagal action on the gastric HCl glands is not specific for gastrin, but a quality shared by gastrin and other hormonal secretagogues.

7184

EFFECT OF ADRENALECTOMY AND GLUCOCORTICOIDS ON THE SECRETION AND ABSORPTION OF HYDROGEN ION. (E.) Cooke, A. R. (VA Ctr., Los Angeles, Cal.), R. M. Preshaw and M. I. Grossman. Gastroenterology 50(6):761-767, 1966.

In Heidenhain pouch dogs, the acid output response to all doses of histamine (0.187-6.0 mg/hr.) was significantly reduced by bilateral adrenalectomy under deoxycorticosterone acetate maintenance. At the highest histamine dose all animals collapsed, but recovery was prompt when histamine infusion was stopped, and hydrocortisone was not needed. The reduction in acid output was due to a reduction in secretion vol., but the relationship between vol. rate and hydrogen ion conc. was unchanged after adrenalectomy. Hydrocortisone restored gastric secretion to normal levels in adrenalectomized dogs, but mineralocorticoids (deoxycorticosterone acetate) did not. Acid absorption by the gastric mucosa was not affected by adrenalectomy and/or steroid admin., indicating that impaired acid secretion in adrenalectomized dogs in response to histamine is not due to increased leakage of secreted acid from the gastric lumen to the blood.

7185

HISTOCHEMICAL EVIDENCE OF TESTOSTERONE-INDUCED STIMULATION OF AMYLASE SECRETION IN THE SUBMAXILLARY AND RETROLINGUAL GLANDS OF MICE. (Fr.) Chrétien, M. (Radium Inst., Paris). C. R. Acad. Sci. (Paris) 262(4) (Ser. D):491-494, 1966.

Amylase secretion was studied (slightly modified Daoust method) in the submaxillary and retrolingual glands of castrated male and intact female albino mice treated by a single s.c. inj. of 5 mg of testosterone propionate. Secretion was markedly stimulated in the tubular portion of the submaxillary gland, parallel to tubular development; no difference was seen in the extent of amylase-positive areas in treated males and females sacrificed at the same time; increased secretion was observed by day 5 and reached a max. at day 10, at which time levels were equal to or greater than those of untreated intact males. In castrated male rats (usually with no amylase activity), treatment with testosterone caused marked increase in amylase secretion (greater than that seen in normal intact males) and in the number of secretory cells lining the intralobular excretory canaliculi. In females, testosterone had a slower and much more reduced effect on amylase activity.

7186

THE INFLUENCE OF PROLONGED TRANSVERSELY DIRECTED RADIAL ACCELERATIONS ON THE SECRETION OF INTESTINAL JUICE AND ENZYMES IN DOGS. (Rus.) Potkin, V. E. Biull. Eksp. Biol. Med. 61(3):43-47, 1966.

Chronic experiments on four dogs were used to study the influence of prolonged transversely directed radial accelerations (8 g-3 min., back-thorax) on the secretion of intestinal juice and enzymes from an isolated (after Thiry) section of the superior part of the small intestine - in periodic secretion, in secretion in response to mechanical irritation on an empty stomach and in secretion in response to mechanical irritation after feeding. During the early days after the radial

SECRETION

accelerations (8 g-3 min.) the secretion of intestinal juice is inhibited. In the subsequent days there appear hypo- and hypersecretion with prolonged period of after-effect (8-9 wk. in 1 of 3 dogs). Enterokinase, amylase and alkaline phosphatase in the first two days remain unchanged but later their activity markedly grows and continues to be increased for a long time. The period of after-effect varied and was in 1 of 3 for amylase = 12 wk., for enterokinase 14 and for alkaline phosphatase 16 wk. Lysozyme activity, however, is, on the contrary, inhibited considerably, the inhibition lasting 5 wk. in 1 of 3. An identical direction was noted in the changes of indices both in secretion during mechanical irritation, periodic secretion on an empty stomach, and during secretion in response to mechanical irritation after feeding; however, the after-effect period was different. In this way, the influence of radial accelerations (8 g-3 min.) serves to produce a considerable change in the functional condition of the small intestine.

- 7187 ISOLATION OF TWO GASTRINS FROM HUMAN ANTRAL MUCOSA. (E.) Gregory, R. A. (U. Liverpool, England), H. J. Tracy and M. L. Grossman. Nature (London) 209(5023):583, 1966.

A technic is described for the isolation from human antral mucosa by gradient elution on aminoethylcellulose in ammonium bicarbonate buffer of 2 heptadecapeptide amines, H.I and H.II. Antra were removed from patients undergoing partial gastrectomy. A typical run revealed the emergence of H.I first followed by H.II, its tyrosine phosphate ester. Highest yields showed a ratio of 1.35 mg of H.I and 0.79 mg of H.II (in contrast to a 3:4 ratio found in hog gastrins). Physiological effects were identical to those described for hog gastrins. Structural and synthetic studies showed that the human gastric antrum peptides differed from those of hog mucosa only in that the methionine residue in position 5 is replaced by leucine. (See also 7188 and 7189.)

- 7188 STRUCTURES OF HUMAN GASTRINS I AND II. (E.) Bentley, P. H. (U. Liverpool, England), G. W. Kenner and R. C. Sheppard. Nature (London) 209(5023):583-585, 1966.

Amino acid analysis of human gastrins H.I and H.II by UV spectroscopy and infrared degradation confirmed the close relationship of human and hog gastrins already suspected from their identical physiological and chromatographic properties. Degradative studies confirmed the presence of 6 glutamic acid residues (as in hog gastrin) and located the leucine residue of H.I at position 5. The latter was further confirmed by the isolation of a pure, ninhydrin-negative di-acidic peptide of composition (Glutamic acid, Glycine, Proline, Tryptophan). No evidence was obtained for any difference between human and hog gastrins apart from the leucine-methionine interchange at position 5. Although results do not prove the structure of human gastrin I in detail, they provide very strong support for the suggested single-residue interchange relationship with hog gastrin. (See also 7187 and 7189.)

- 7189 SYNTHESIS OF HUMAN GASTRIN I. (E.) Beacham, J. (U. Liverpool, England), P. H. Bentley, R. A. Gregory, G. W. Kenner, J. K. MacLeod and R. C. Sheppard. Nature (London) 209(5023):585-586, 1966.

A procedure is described for the synthesis of human gastrin I which involves coupling the N-terminal pentapeptide by the azide method with a (6-17) dodecapeptide amide. The product was purified by chromatography on aminoethylcellulose. Upon rechromatography, it was eluted as a single peak like natural human gastrin I, and was indistinguishable by electrophoresis. On the other hand, the lower homologue prepared in the same way from the (7-17) undecapeptide amide had different electrophoretic mobility ($E_{6,15}^{glu} = 0.65$ instead of 0.7). Thus, the ambiguity concerning the content of glutamic acid was removed. The heptadecapeptide amide was fully active in stimulating gastric secretion, and its identity with human gastrin I was confirmed by parallel degradation of natural and synthetic hormones by papain and by thin layer chromatography of peptide patterns. (See also 7187 and 7188.)

- 7190 CIRCULATORY EFFECTS OF A SYNTHETIC GASTRIN-LIKE PENTAPEPTIDE (I.C.I. 50,123). (E.) Logan, C. J. H. (Queen's U., Belfast, Ireland), I. Brick and I. C. Roddie. Lancet 1(7445):999-1000, 1966.

SECRETION

Arterial blood pressure, heart rate and forearm or hand blood flow increased only slightly in 3 healthy men who received a 3 min. i.v. infusion of the synthetic gastrin-like pentapeptide I.C.I. 50,123 (0.5 µg/kg). These circulatory changes occurred near the end of the 3-min. period when subjective sensations (epigastric burning, faintness, and slight nausea) were greatest. Only slight epigastric burning and no circulatory changes were recorded when the same dose was admin. intra-arterially, which would seem to eliminate histamine release as the cause for the slight circulatory changes previously mentioned.

- 7191 COMPOSITION AND STABILITY OF THE ENZYMATIC APPARATUS OF THE PANCREAS OF MAN AND OF VARIOUS ANIMALS. (Fr.) Figarella, C. (Sainte-Marguerite Hosp., Marseille, France). Bull. Soc. Chim. Biol. (Paris) 48(1):97-115, 1966.

Homogenates of rat, cattle, swine, dog and human pancreatic tissue were tested for amylase, lipase, chymotrypsinogen and trypsinogen activity. All 4 were present in man and none were abnormally low. However, levels of specific activity were only fair, as compared to the other species, possibly due to the fact that specimens were derived from patients undergoing surgery, although none had a pancreatic disorder as such. In cattle, proteolytic enzymes accounted for approx. three-fourths the total. The relatively highest activity, and the most nearly balanced, was seen in swine and rats, with dogs occupying a position midway between these and man. The effects of activating trypsin on trypsinogen were found to be max. for all species at a level of 2% the total protein content of the homogenate. At this level, trypsinogen became fully activated in 2-4 and 15 hr. in man and the rat, resp., while dogs, swine and cattle required 20-24 hr. In all species, no activity took place when trypsin dropped below a level of 0.20%-0.30%. Activation inhibitors in the homogenates were demonstrable in man at a relatively high level; at a somewhat lower level in dogs and cattle. Neither activators nor inhibitors were demonstrable in rat pancreatic homogenates; while those of swine showed only a progressively increased activation effect with increased dosage, possibly due to the presence of free trypsin.

- 7192 GASTRIC FUNCTION AND STRUCTURE IN IRON DEFICIENCY. (E.) Shearman, D. J. C. (Royal Infirm., Edinburgh, Scotland), I. W. Delamore and D. L. Gardner. Lancet 1(7442):845-848, 1966.

Gastric function by means of the augmented histamine secretion test and the histamine infusion test was studied in 17 patients presenting with moderate to severe iron-deficiency anemia. HCl secretion was depressed in 9 patients, while 8 patients were achlorhydric. Parietal cell antibodies were demonstrated in 7 of 8 achlorhydric patients, but not in any of the patients who secreted acid. None of the 8 achlorhydric patients had antibodies to intrinsic factor, but 3 had an abnormal Schilling test (corrected by intrinsic factor), 2 had equivocal absorption, and 2 had a low conc. of pernicious anemia vitamin B₁₂ in the serum. Gastric biopsy in achlorhydric patients showed absence of parietal cells and chronic atrophic gastritis; of 5 patients with acid, biopsy revealed partial glandular atrophy in 1 and varying degrees of chronic atrophic gastritis in 3. It is suggested that while the reduction in HCl secretion might be in part secondary to the changes of chronic atrophic gastritis, a contributing factor is a functional defect of the parietal cell which can be overcome, in time, by treatment of the iron-deficiency anemia.

- 7193 A RADIOIMMUNOASSAY FOR HUMAN INTRINSIC FACTOR. (E.) Rothenberg, S. P. (New York Coll. Med., N. Y.). J. Lab. Clin. Med. 67(5):879-890, 1966.

A radioimmunoassay for human intrinsic factor is presented based on the competitive inhibition of antibody binding of radioactive B₁₂-labeled intrinsic factor by unlabeled intrinsic factor. Since purified human intrinsic factor was not yet available, the standard curve used for reference was made by assaying dilutions of pooled normal gastric juice. The posthistamine gastric juice from a group of normal subjects, patients with histamine fast achlorhydria, and patients with pernicious anemia had intrinsic factor levels of 32-179%, 12-63%, and 0-6.6%, resp. Although blood group substance B did not competitively inhibit the antibody from binding tracer intrinsic factor, substance A had a slight inhibitory effect which corresponded to approx. 1.5% intrinsic factor on the standard curve. Boiling the gastric

SECRETION

uice reduced the intrinsic factor content from 63 to 4.3% and from 153 to 4.9% in the 2 samples subjected to this procedure. Hog intrinsic factor cross-reacted with human antihuman intrinsic factor antibody. One sample of human bile assayed had no intrinsic factor. The advantages of this method are discussed.

- 194 ROLE OF BILE DUCTS DURING SECRETIN CHOLERESIS IN DOGS. (E.) Wheeler, H. O. (Columbia U. Coll. Phys. Surg., New York, N. Y.) and P. L. Mancusi-Ungaro. Am. J. Physiol. 210(5):1153-1159, 1966.

trained, unanesthetized, cholecystectomized female mongrel dogs were infused with secretin via indwelling catheters in hepatic artery, splenic vein, and peripheral vein. Increments in bile flow were 1.5 times greater during hepatic arterial than during splenic venous infusion and 1.2 times greater during splenic venous than during peripheral venous infusion. Increments in bicarbonate excretion rate showed similar relationships. Since bile ducts are supplied mainly by hepatic artery this suggests that secretin acts mainly on the duct system, but responsive tissue must also receive at least part of its blood supply from the portal vein. In other studies sulfobromophthalein was infused at constant rate and the quantity of extra sulfobromophthalein washed out during secretin or taurocholate cholerisis was used to calculate an apparent biliary "washout vol." This was 0.5-3 ml less during secretin than during taurocholate cholerisis. The results of both types of experiments indicate that mechanisms responsible for secretin cholerisis are located in the bile ducts or ductules.

- 195 RAT BILE TREE DURING REFLUX PERFUSION. (E.) Barber-Riley, G. (U. Malaya, Kuala Lumpur, Malaysia). Am. J. Physiol. 210(5):1137-1141, 1966.

Experiments were performed on female adult albino rats (Sprague-Dawley) with increased intrabiliary pressures which were produced by reflux perfusion of the bile duct. The secretory mechanism showed no permanent impairment with perfusion rates producing pressures greatly in excess of that resulting from obstruction of the bile duct when applied for short periods of time. In repeated experiments on the same animal measured capacity increased slightly with perfusion rates of 0-52 $\mu\text{ml}/\text{min}$. but was reduced over the range 125-520 $\mu\text{ml}/\text{min}$. Repeated perfusion alone appeared to be only partly responsible for this reduction. Max. vol. available to perfusate was about 65% of max. capacity and showed small increases over the range 52-520 $\mu\text{ml}/\text{min}$. The distended capacity of ethionine-treated rats showed small increases over the range 0-520 $\mu\text{ml}/\text{min}$. The resistance to reflux flow offered by the biliary tract was measured over the range 0-300 $\mu\text{ml}/\text{min}$. It is concluded that in acute experiments little further distention of the biliary tract occurs at pressures in excess of that resulting from obstruction of the common duct. The reduced capacity observed with increased perfusion rates did not seem due to altered resistance to reflux flow. It may be due to temporary change in secretion rate of hepatic cells.

- 196 ACID RESPONSE TO GASTRIN AND RELATED PEPTIDES. (E.) Konturek, S. (VA Ctr., Los Angeles, Cal.) and M. I. Grossman. Gastroenterology 50(5):650-652, 1966.

Studies were performed in 2 female dogs, each having both a Heidenhain pouch of the oxyntic gland area and a fistula of the main stomach. The max. acid secretory response of the Heidenhain pouch to Gastrin II and several synthetic peptides related to gastrin was lower than to histamine. The max. response of the gastric fistula (vagally innervated) was about 20% higher with gastrin than with histamine, a finding similar to that reported for the intact stomach of man. The 3 peptides studied were the C-terminal, tetrapeptide of gastrin, tryptophyl:methionyl:asparagyl:phenylalanine; and the carbamoyl and β -alanyl derivatives of that tetrapeptide. Although all of these peptides were more potent than histamine on a wt. basis, none was as potent as gastrin and only the β -alanyl pentapeptide gave a max. response equal to that of gastrin.

- 197 COMPARISON BETWEEN HISTALOG AND HISTAMINE AS STIMULANTS OF MAXIMAL GASTRIC SECRETION IN MAN. (E.) Laudano, D. M. (Centenario Hosp. Sch. Med., Rosario, Argentina). Gastroenterology 50(5):653-656, 1966.

SECRETION

Gastric secretion was studied in 20 men and 10 women, with an age range from 21-45 yr. On the basis of radiologic findings and basal gastric secretion, 26 were healthy subjects, 3 had duodenal ulcer, and 1 had gastritis. The time course of the secretory response to the 2 stimulants differed. Peak rates of secretion were maintained for 30-45 min. with histamine and for 45-90 min. with betazole. During the first hr. after inj., the mean responses of the 2 agents were about equal. During the second hr. after inj. the mean response to betazole was higher than to histamine. For the full 2-hr. period of collection in 26 normal subjects the mean secretion of HCl after histamine was 44 mEq, after betazole, 61.9 mEq; this difference was statistically significant. Betazole also produced higher peak rates of secretion.

- 7198 OBSERVATIONS ON THE BILE SECRETION IN CULTIVATED LIVER TISSUE. (E.) Sandström, B. (U. Uppsala, Sweden). Acta Soc. Med. Upsal. 71(1-2): 14-20, 1966.

Liver tissue from 15-day-old chicken embryos was cultivated according to a previously described technic with some later modifications. When the explants had been cultivated for 4 days, sodium fluorescein was added to the refeeding mixture. One hr. after feeding, when examined by UV light, the cellular interspaces between more centrally situated cells could sometimes be distinguished by a slightly stronger fluorescence than that of the cytoplasm. This difference was more pronounced after 2 hr. After 12 hr. these bile canaliculi were no longer detectable by their fluorescence. These observations indicate that the cells were able to eliminate bile into bile canaliculi, although at a low rate.

- 7199 β -BENZALBUTYRIC ACID AND ITS DERIVATIVES AND QUALITATIVE AND QUANTITATIVE BILE CHANGES. (It.) Valcalvi, U. and N. Bolego Zonta. Gior. Arterioscl. 3(2):265-269, 1965.

Variations in bile flow and content were studied in Wistar rats (av. wt. 300 g) after the admin. of β -benzalbutyric acid or its amide by various routes. After admin. of 25-250 mg/kg by the intraduodenal route, max. bile flow was observed 1-2 hr. after admin. of the choleretic at all dosage levels, while bile flow was best maintained with doses of 100 mg/kg. β -Benzalbutyric acid was less choleretic than dehydrocholic acid, but its effect lasted longer (60% above basal bile flow values after 5 hr.) than that of the latter (return to basal values after 3 hr.). The choleretic effect of β -benzalbutyramide was less than that of β -benzalbutyric acid. At doses of 100 mg/kg, max. bile flow occurred within 1 hr. (100%) following intraduodenal or i.v. admin. and within 3 hr. (75%) following i.m. admin. of β -benzalbutyric acid the effect on bile flow was maintained in subsequent hr. An increase in the elimination of solid bile components was seen in treated (100 mg/kg intraduodenally) animals within the first 4 hr. as compared to untreated controls; total dry bile residue was decreased in both treated and control animals.

- 7200 EFFECT OF GAMMA IRRADIATION ON SALIVARY SECRETION IN MAN. (It.) Nannello, M. (U. Florence, Italy), L. Tomasetti and T. Ricci. Rass. Derm. Sif. 18(6):215-227, 1965.

Salivary viscosity was determined in 70 laryngectomized patients subjected to radium treatment (total Roentgen units = 6,500) of the laterocervical lymphatic chain for glottic-supraglottic or marginal cancer (50 patients; high collar; Group 1) or glottic-subglottic cancer (20 patients; low collar; Group 2). Laryngectomy had no effect on salivary viscosity, since values were the same before and after surgery. Parotid saliva viscosity was slightly increased in Group 1 after radium therapy, reached a peak (1.9-2.4) after 1-2 mo., and returned to normal 4 mo. after completion of treatment; in Group 2, viscosity was only slightly increased, with return to normal by mo. 3; Group 1 also showed marked variations in the quantity of saliva secreted. Submaxillary saliva viscosity was increased to values of 0.3-0.9 following radium therapy in Groups 1 and 2, with return to pre-radiation values by 7 and 5-6 mo., resp. Total (parotid and submaxillary) saliva viscosity was also slightly increased, with return to normal values in less time than that of submaxillary saliva. At 37°C, total saliva viscosity decreased to values similar to those of distilled water within 1-2 hr. (values were identical before and after

SECRETION

laryngectomy); following radium therapy, total saliva viscosity in both groups reached distilled water values after a longer time than untreated laryngectomized patients, with values higher than those of distilled water even after 5-6 hr. in some cases; at 4-5 mo. after radium therapy, total saliva viscosity decreased more rapidly, with return to pre-radiation values within 7 mo. In all patients examined 1-3 yr. after radium therapy, parotid, submaxillary, and total saliva viscosity values were similar to those seen before radiation. Results indicate that the qualitative changes in saliva secretion as a result of radium therapy are temporary and reversible.

- 7201 EFFECT OF TRASYLOL ON PANCREATIC SECRETION. (Ger.) Schönbach, G. (U. Giessen, Germany), F. X. Sailer, D. Stamm, G. Kümmel and H. D. Moller. Klin. Wschr. 44(11):652-653, 1966.
In normal rabbits, treatment with Trasylol (25,000 U/kg i.v.) caused no significant immediate decrease in the vol. of spontaneous pancreatic secretion (av. 0.30 and 0.28 ml/hr., resp.), but caused a significant decrease in pancreatic trypsin activity (av. 8.94 and 2.79 I.U./hr., resp.). A larger dose of Trasylol (50,000 U/kg i.v.) caused significant decreases in both pancreatic secretion vol. and trypsin activity (av. values 0.13 ml/hr. and 3.42 I.U./hr., resp.) after 24 hr. No change in pancreatic secretion was seen immediately after Trasylol admin. The significance of this atropine-like action in the treatment of acute pancreatitis is discussed.
- 7202 ASPECTS OF PHYSIOLOGY OF THE EXOCRINE PANCREAS. (Fr.)(Rev.) Bauduin, H. (Free U. Brussels Sch. Med., Belgium) and J. J. Reuse. Acta Gastroent. Belg. 29(2):153-162, 1966.
- 7203 SECRETION OF GLYCOPROTEINS IN THE GOLGI APPARATUS OF RAT HEPATIC CELLS; RADIOAUTOGRAPHIC STUDIES BY ELECTRON MICROSCOPY FOLLOWING GALACTOSE-H INJECTION. (Fr.) Droz, B. (Atom. Energy Comm., C.E.N., Saclay, Gif-sur-Yvette, Essonne, France). C. R. Acad. Sci. (Paris) 262(16)(Ser. D):1766-1768, 1966.

- 7205 GASTRIC SECRETION. (Nor.)(Rev.) Myren, J. (Ulleval Hosp., Norway), L. S. Semb and E. Gjone. T. Norsk. Laegeforen. 86(11):855-859, 1966.

DIGESTION

- 7206 DISTRIBUTION AND PROPERTIES OF AMINO ACID DECARBOXYLASES IN GASTRIC MUCOSA. (E.) Håkanson, R. (U. Lund, Sweden) and C. Owman. Biochem. Pharmacol. 15(4):489-499, 1966.

Both C^{14} -labeled and unlabeled decarboxylases were employed. In the rat, β -(3,4-dihydroxyphenyl)-L-alanine (l) and histidine decarboxylases occurred exclusively in the pyloric region of the stomach. In the rabbit, l decarboxylase was found predominantly in the fundic region; in this species the histidine decarboxylase activity was too low to permit estimation. A partially purified preparation of histidine decarboxylase from rat stomach had properties very similar to those of histidine decarboxylase from fetal rat tissues. A histamine-forming enzyme could also be extracted from rabbit stomach but this enzyme had properties identical with those of l decarboxylase which is unspecific and attacks all aromatic amino acids including histidine. The l decarboxylase could be demonstrated in the stomach wall of all species studied; so far, the specific histidine decarboxylase has been demonstrated in rat stomach only. After i.p. inj. of l or 5-hydroxytryptophan to rats, large amounts of dopamine or 5-hydroxytryptophan accumulated in the gastric mucosa, indicating that the l decarboxylase in the stomach wall is active in vivo. The amines were located in an enterochromaffin-like cell system in the pyloric part of the gastric mucosa as revealed by fluorescence microscopy. Preliminary evidence indicate that the amines were produced within these cells. The high l decarboxylase activity in the gastric mucosa of the species studied may indicate an important role for this enzyme in gastric function.

- 7207 RELIABILITY OF POLYETHYLENEGLYCOL AS AN INDICATOR FOR DIGESTION STUDIES WITH SWINE. I. RATE OF PASSAGE OF POLYETHYLENEGLYCOL THROUGH THE DIGESTIVE TRACT. (E.) Ishikawa, S. (Mie U. Sch. Agr., Tsu, Japan). Agr. Biol. Chem. 30(3):278-284, 1966.

Polyethylene glycol (molecular wt. 4000) was removed from the stomach more rapidly than chromic oxide after admin. in feed, and was somewhat delayed in passage through the colon because of water absorption. Excretion variations of both indicators were substantially the same; fecal recovery of polyethylene glycol was lower than that of chromic oxide. There was no essential difference in retention time in the digestive tract between the 2 indicators. The low fecal recovery rate for polyethylene glycol (70-80% after 60-66 hr.) as compared to chromic oxide (82-90%) was considered to be unfavorable for the use of polyethylene glycol as an indicator.

- 7208 CHARACTERIZATION OF HYDROLASES OF THE HUMAN PANCREAS. (Fr.) Tan, King Bien (Inst. Sci. Res. Cancer, Villejuif, France), M. Vicomte, S. Avrameas and J. Uriel. C. R. Acad. Sci. (Paris) 262(6) (Ser. D):716-718, 1966.

Immunoelectrophoretic and other enzyme identification studies were performed on acetone extracts of human pancreas. The antigen-antibody complexes formed in tests using total pancreatic anti-extract antiserum were identified as chymotrypsin (similar to chymotrypsin A of pig and beef pancreas), elastase (similar to type I found in pig pancreas), trypsin (shown to possess a hydrolytic effect on casein and phenylalanine ester but not on benzoyl-DL-arginine naphthylamide), leucine aminopeptidase, lipase, α -amylase, and carboxypeptidase A and B.

- 7209 STUDIES ON HUMAN PANCREATIC LIPASE. (E.) Fraser, G. P. (U. Aberdeen, Scotland) and A. D. Nicol. Clin. Chim. Acta 13(5):552-562, 1966.

Pancreatic juice, obtained by duodenal drainage from patients undergoing pancreatic surgery, was subjected to column chromatography; the "fast" (high molecular wt.) component, which had no proteolytic activity or amylase, was studied further. This fraction differed from pig pancreas enzyme in being inhibited by high conc. of substrate, but in this respect it resembled a human leukocyte lipase sample. This pancreatic juice lipase was not potentiated by bile salts; in fact, its activity was inhibited by taurocholate and deoxycholate at high conc. Calcium ions had no effect on the enzyme, but human serum (from normal subjects or patients with pancreatitis)

GESTION

used marked inhibition of purified preparations. The inhibitory effect of albumin of the same order as that produced by serum containing equivalent amounts of albumin. Bovine albumin was more inhibitory than human albumin; the amount of inhibition depended upon the order in which the lipase and albumin were added to the substrate. This inhibition was reversed by deoxycholate. The lipase fraction was stable in a 1% gum acacia-0.14 M saline soln.; it had no dialyzable cofactor.

- 10 INVESTIGATION OF THE DIGESTIBILITY OF PROTEIN FROM ANIMAL AND VEGETABLE SOURCES WITH AND WITHOUT ADDITIONAL FAT. I. THE COURSE OF GASTRIC EMPTYING. (Ger.) Canzler, H. (Max Planck Inst. Nutr., Dortmund, Germany) and H. Glatzel. Nutr. Dieta (Basel) 8(1):49-60, 1966.

10 healthy men were fed meals of equal protein and carbohydrate content (29.1 and 45 g, resp.) but varying in fat content (9.3 or 33.6-33.8 g) and with protein from animal or plant sources. The course of gastric emptying was followed 10 min.-5 hr. after the meal. In the first 90 min., the rate of gastric emptying depended on the source of protein. With a high- or low-fat meal containing vegetable protein, gastric emptying was delayed as compared to the digestion of the animal protein meal. After 90 min., the rate-determining factor was the fat content of the meal; emptying of both types of low-fat meal was significantly more rapid than that of the high-fat meals. For purposes of comparison, the degree of emptying at a particular time (e.g., 180 min.) was a more useful measurement than the exact time when gastric emptying was complete, because the rate of gastric emptying varied from one subject to another.

- 11 EFFECT OF LYSINE DEFICIENCY ON HYDROLASE CONTENT OF RAT PANCREAS AND SMALL INTESTINE. (Fr.) Vandermeers, A. (Free U. Brussels, Belgium), P. Robberecht, J. Rathé and J. Christophe. Bull. Soc. Chim. Biol. (Paris) 48(1):133-153, 1966.

11 young rats, 3-wk. feeding with gluten as the sole protein resulted in severe lysine and subacute threonine deficiencies, accompanied by complete arrest of growth. Growth arrest appeared to be due to the protein deficiency, a diminution of tissue sensitivity to thyroxine, diminution of the secretion of growth hormone and impotence in the transport of vitamin A into blood plasma. The mitotic index was extremely low, with dissolution of the apex of acinar cells and a severe decrease of pancreatic nucleic acids, amylase, chymotrypsinogen, trypsinogens, lipase and procarboxypeptidase-B. Effects on total protein content were more severe in the exocrine pancreas than they were in the liver or in adipose tissue, and all pancreatic enzymes appeared to be excreted more rapidly than they could be synthesized. Within 3 days of restoration of a normal diet, the mitotic index of the acinar cells had increased 10 times and the apices were normal in size and filled with hydrolases. In general, the major changes in the conc. of pancreatic enzymes (and especially of amylase and chymotrypsinogen) took place within 24 hr. of beginning the protein-impo-

- 12 DEMONSTRATION OF A PHOSPHATIDASE-A IN THE PANCREATIC SECRETIONS OF MAN AND THE RAT. (Fr.) Belleville, J. (U. Dijon Fac. Sci., France) and J. Clement. Bull. Soc. Chim. Biol. (Paris) 48(1):186-189, 1966.

12 following incubation of pancreatic secretion (derived from the rat or from human subjects) with lecithin or lecithin + sodium deoxycholate, degradation of lecithin to lysolecithin was demonstrable chromatographically, as was the degradation of combinations of cephalin with ethanolamine or serine. The phosphatidase-A responsible for the phenomenon was shown to be thermostable. The speed of reaction was the same in the presence of a borate or phosphate buffer, pH 7.2; no reaction took place in the presence of an acetate buffer, pH 4.5. Pancreatic secretion derived from human subjects achieved the same degree of degradation of lecithin in 2 hr. as was achieved by rat pancreatic secretion in 24.

- 13 PANCREATIC LIPASE ACTIVITY IN DEUTERIUM OXIDE. (E.) Thomson, J. F. (Argonne Nat. Lab., Ill.), K. J. Bush and S. L. Nance. Proc. Soc. Exp. Biol. Med. 122(2):502-505, 1966.

DIGESTION

As measured by estimates of maximal reaction velocities, the activity of purified porcine pancreatic lipase (with tributyrin emulsified in gum arabic as substrate) was inhibited progressively and linearly by increasing conc. of deuterium oxide up to 100%. However, the percentage inhibitory effects of particular conc. of deuterium oxide were reduced (although not in direct proportion) by reductions of the substrate conc., suggesting a stronger (solvent) effect on enzyme-substrate binding than on the rate of hydrolysis as such.

MOTILITY

- 21 THE DISTRIBUTION OF IONS IN THE SMOOTH MUSCLE OF THE GUINEA-PIG TAENIA COLI. (E.) Buck, B. (U. Oxford, England) and P. J. Goodford. J. Physiol. (London) 183(3):551-569, 1966.

The distribution and composition of ions of smooth muscle of guinea pig taenia coli was studied at 4 and 35°C. The rate of loss of Na²⁴ was temperature dependent with an av. Q₁₀ of 3.4 on warming in the range of 4-35°C. Exponential analysis of Na²⁴ flux at 35°C showed an initial rapid phase, a second phase with T_{1/2} = 2 min. which was most sensitive to temperature change, and a slowly exchanging phase. The loss rate of Na²⁴ was reduced in K-free or Na free soln. The cell size increased at 4°C and fell again on rewarming while Na and Cl left the cell and K was taken up. Cell Cl content was linearly related to cell size. It is concluded that the quiescent smooth muscle cell membrane was more permeable to sodium than skeletal muscle cell membrane.

- 22 APPLICATION OF THE SUCROSE-GAP METHOD TO DETERMINE THE IONIC BASIS OF THE MEMBRANE POTENTIAL OF SMOOTH MUSCLE. (E.) Bennett, M. R. (U. Melbourne, Australia) and G. Burnstock. J. Physiol. (London) 183(3):637-648, 1966.

In vitro studies on guinea pig ureter indicated that if the ionic environment of the cells was uniformly changed, then the potential change recorded by the sucrose gap was proportional to the magnitude of the short circuit factor, the liquid junction potential change and the amplitude of the membrane potential change of a single cell. When the extracellular potassium conc. was changed reciprocally with the extracellular chloride conc. to maintain the Donnan equilibrium across the muscle membrane, the membrane potential was found to decrease by 53 mV for a 10 fold-change in external K conc. for conc. above 10 mM. A simple method was described for determining the steady value of the short circuiting factor and the liquid junction potential changes so that the recorded potential could be corrected to give membrane potentials. The effect of isotonic K₂SO₄ and KCl on ureter smooth muscle membrane potentials is described. It is concluded that above an external K conc. of 10 mM the ureteral smooth muscle membrane potential obeys the prediction of the Nernst equation for a K electrode.

- 23 EFFECT OF N,N'-[α-(1-NAPHTHYL)-PROPIONYLOXY-2-ETHYL]-PIPERAZINE CHLORHYDRATE (NAPHTHIMEPEZINE) ON SMOOTH MUSCLE IN VITRO. (It.) Bertolini, A. (U. Modena, Italy), M. Bernardi and P. Mucci. Boll. Soc. Ital. Biol. Sper. 42(2):41-44, 1966.

The effect of naphthimepezine was studied in vitro on the smooth muscle of guinea pig small intestine and rat uterus and gastric fundus. In conc. of 5×10^{-6} , the drug inhibited the spastic effect of acetylcholine (1×10^{-7}), histamine (1×10^{-6}), primum chloride (1×10^{-4}), and serotonin (1×10^{-6}) on ileal smooth muscle. Using the Vane test, naphthimepezine in conc. of 3×10^{-5} inhibited the response of the gastric fundus to serotonin (3×10^{-8}). The drug also showed an inhibitory effect on uterine tone and motility.

- 24 RESPONSES OF THE ISOLATED ILEUM OF THE MORPHINE-TOLERANT GUINEA PIG. (E.) Takagi, K. (U. Tokyo, Japan), I. Takayanagi, T. Irikura, K. Nishino, N. Ichinoseki and K. Shishido. Arch. Int. Pharmacodyn. 158(1):39-44, 1965.

The response of isolated ileal segments to various drugs was studied in morphine-tolerant (induced by repeated daily s.c. inj. of morphine hydrochloride) guinea pigs. The response of the isolated ileum to serotonin and morphine were accelerated, while the response to acetylcholine chloride, L-nicotine-bi-D-tartrate, and hexamethonium bromide were unchanged. This indicates that the acceleration of spontaneous movements might be related to nerve excitation and not to the accumulation of acetylcholine due to the anticholinesterase activity of morphine. Response of the ileum to serotonin was inhibited by morphine and levallorphan. The anticholinesterase activity of morphine was not observed following single or repeated admin. of morphine. The admin. of morphine by s.c. inj. failed to inhibit the action of serotonin, despite the fact that morphine is supposed to combine with its receptor on the nerve in the small intestine.

MOTILITY

- 7225 STUDIES ON THE INTRACELLULAR GRANULES OF THE INTESTINAL SMOOTH MUSCLES. I. ATPase ACTIVITY. (Jap.) Totsuka, M. (Sapporo Coll. Med., Japan). Sapporo Igaku Zasshi (Sapporo Med. J.) 27(5-6):268-274, 1965.

In order to determine the mechanism of contraction and relaxation in intestinal smooth muscle, the ATPase activity of the microsomal fraction (12,000-67,500 times gravity) obtained from homogenates of dog intestine smooth muscle was studied. Electron microscope studies revealed the presence in this fraction of small vesicles (1,000-2,500 Å in diameter), mitochondrial fragments, and an unidentified contaminant in the background. Microsomal ATPase activity was 3 times greater in intestinal smooth muscle than in striated muscle under the same experimental conditions. ATPase activity was markedly stimulated by the presence of Mg^{++} ions, inhibited by definite conc. of Mg^{++} and Ca^{++} , and slightly stimulated by the absence of Mg^{++} and Ca^{++} . ATPase activity was not influenced by changes in KCl conc. 2,4-Dinitrophenol (5 mM) and ouabain (0.1 mM) inhibited ATPase activity by approx. 20%, while azide (5 mM) stimulated it by approx. 40%. The similarity of this ATPase activity to that of Kielley-Meyerhof and the possibility that this microsomal fraction may have the same function as that of striated muscle are discussed.

- 7226 SIMULTANEOUS STUDIES OF THE ELECTRICAL ACTIVITY OF LONGITUDINAL AND CIRCULAR SMOOTH MUSCLE FIBERS OF THE RABBIT DUODENUM IN VITRO. (Fr.) Gonella, J. (U. Marseille Sch. Sci., France) and H. Gignoux. C. R. Acad. Sci. (Paris) 262(5) (Ser. D):570-573, 1966.

A method is described for the simultaneous electromyographic registration of electrical activity of both longitudinal and circular smooth muscle fibers using the same electrode. A 6-8 cm segment of rabbit duodenum in physiological saline maintained at a temperature of 27-37°C was used. Upon formation of an opening (2 mm²) in the longitudinal muscle layer, it was possible to place an electrode directly on the circular layer and register its electrical activity. Careful histological examination must be conducted to make sure that the circular layer has not been damaged in the process. Results indicate that the electrical activity of the circular fibers is composed of potentials whose appearance coincide with contraction of the circular musculature and is accompanied by an increase in the intraluminal pressure of the intestine. During peristalsis, this electrical activity appears at one end of the preparation and is propagated to the opposite end; during pendular movements, no electrical activity is registered. The electrical potentials of the circular fibers are of a greater amplitude than those of the longitudinal fibers. This apparently paradoxical result (since the electrode is closer to the longitudinal layer) is explained by the fact that the width of the circular layer is greater and the electrical activity of the longitudinal layer which is registered is that of the non-depolarized portion farthest away from the electrode.

- 7227 THE EFFECT OF A SYNTHETIC GASTRIN-LIKE PENTAPEPTIDE (I.C.I. 50,123) ON INTESTINAL MOTILITY IN MAN. (E.) Logan, C. J. H. (Queen's U., Belfast, Ireland) and A. M. Connell. Lancet 1(7455):996-998, 1966.

Admin. of a synthetic gastrin-like pentapeptide (I.C.I. 50,123; i.v., 0.25-0.5 µg/kg) to 3 volunteers consistently caused increased activity of the sigmoid colon and rectum. The onset of activity varied from 1 experiment to the next and was not related to dosage. This same dosage also caused a slight increase in ileal activity but, since saline soln. gave a somewhat similar response, these results are inconclusive. No consistent effects on motility were seen following s.c. admin. of this peptide (1-4 µg/kg). Pressure changes were measured in the large intestine by miniature balloons and in the small intestine by pressure-sensitive radiotelemetering capsules.

- 7228 DATA ON THE EFFECT OF 2-NAPHTHYL-1-METHYLIMIDAZOLIN HYDROCHLORIDE ON THE GASTROINTESTINAL TRACT. (Ger.) Bakó, G. (Kalocsa City Hosp., Hungary) and J. Szegi. Pharmazie 21(4):238-240, 1966.

In isolated rat small intestine preparations, admin. of the title compound (naphthazolin) in 3 small increments (1, 10, and 100 µg/ml) did not affect either peristalsis or tonus, but addition of a further 100 µg/ml caused an increase in

peristalsis and a slight reduction in tonus. Substitution of this medium by fresh Tyrode's soln. containing no naphazolin did not reverse this effect; the peristalsis was marked and continuous. Addition of 10 and 100 $\mu\text{g/ml}$ of naphazolin under these conditions caused an increase in peristalsis without affecting tonus; this effect was promptly reversed by epinephrine (10 $\mu\text{g/ml}$), showing that naphazolin has no epinephrine-like action. The spasmogenic effect of barium chloride (100 $\mu\text{g/ml}$) was antagonized by epinephrine (1 $\mu\text{g/ml}$), while naphazolin itself (10 $\mu\text{g/ml}$) had no effect. It is suggested that the amphomimetic action of naphazolin is secondary to a release of acetylcholine.

- 229 STRUCTURE-ACTIVITY RELATIONSHIPS IN ANTISPASMODIC COMPOUNDS CHEMICALLY RELATED TO N,N'-DI[α -(1-NAPHTHYL)-PROPIONYLOXY-2-ETHYL]PIPERAZINE (NAFIVERINE). (E.) Pala, G. (De Angeli S. p. A., Milan, Italy), A. Mantegani and C. Turba. Arzneimittelforschung 16(3):393-395, 1966.
- The antispasmodic effects of Nafiverine derivatives were tested in guinea pig ileum preparations in vitro, using acetylcholine (10^{-7} M), histamine (10^{-6} M), barium chloride (10^{-4} M), or nicotine (2×10^{-6} M) as spasmogenic agents. Greatest activity was seen with compounds in which N,N'-di(2-hydroxyethyl)piperazine was esterified with 1-naphthylacetic acids; when the substituents on the α -methylene group were the same, esterification with 2-naphthylacetic or phenylacetic acid led to a decrease in activity. Saturation of naphthalene in positions 5, 6, 7, and 8 led to a slight decrease in potency, but this compound (N,N'-di[α -(1-naphthyl-5,6,7,8-tetrahydro)propiionyloxy-2-ethyl]piperazine 2 HCl), like Nafiverine, caused 100% inhibition of the effects of all the above spasmogenic compounds at the indicated conc. An equally effective agent was N,N'-di(α -phenyl- β -hydroxypropionyloxy-2-ethyl)piperazine-2 HCl. Highest activity was seen when the carboxyl group was separated from naphthalene by a single carbon atom; when the carboxyl group was attached directly to the naphthalene, or separated from it by 2 carbon atoms, a sharp decrease in activity was noted. The number and type of substituents in the α -methylene group were very important; in all series studied, optimum activity was seen when the substituent was a single short aliphatic radical (methyl, ethyl, hydroxymethyl). With longer or unsaturated substituents, or with double substituents, the compounds had decreased antispasmodic activity; some of them, in fact, were spasmogenic.

- 230 STUDIES ON THE PHARMACOLOGICAL EFFECT OF PECTIN ON INTESTINAL MOVEMENTS. THE EFFECT OF PECTIN ON THE CHOLINESTERASE ACTIVITY OF SMALL INTESTINE OF RATS. (Jap.) Fujimori, Y. Hirosaki Igaku (Hirosaki Med. J.) 17(2):435-451, 1965.
- 231 STUDY OF THE MOTILITY OF THE EXTRAHEPATIC BILIARY TRACT IN THE COMMON CARP (Cyprinus carpio L.) BY RADIOGRAPHY WITH A CONTRAST MEDIUM. (Fr.) Laporte, C. (U. Montreal Sch. Sci., Canada), A. Serfaty and J. M. Demers. Rev. Canad. Biol. 25(1):1-10, 1966.

HEPATIC METABOLISM

- 7232 ENTEROHEPATIC CIRCULATION AND THE METABOLISM OF SEX HORMONES IN MAN. (Ger.) Bolt, W. (U. Cologne, Germany), F. Ritzl and H. M. Bolt. München Med. Wschr. 108(16):875-878, 1966.

Following i.v. inj. of tritiated testosterone into a postmenopausal subject, the authors estimated that at least 50% of the resulting estrogens passed through the enterohepatic circulation, although no significant amounts of testosterone or 17-ketosteroids appeared to do so. In another postmenopausal patient with a biliary drain (following cholecystectomy), a similar inj. was followed within 90 min. by demonstrable radioactivity in the bile. Inj. of tritium-labeled cortisol almost doubled the amount of activity demonstrated. Approx. equal amounts of the testosterone inj. proved to have been transformed into biliary estrogens (estriol, 16-epiestriol, estradiol and estrone) and biliary 17-ketosteroids, resp., while radioactive testosterone could not be demonstrated in the bile. It is concluded that active excretion of estrogens may be a significant part of the secretory activity of the hepatic parenchyma.

- 7233 SURVIVAL OF HEPATECTOMIZED DOGS WITH PARTIAL LIVER TRANSPLANTS. (E.) Van Der Heyde, M. N. (Union U. Coll. Med., Albany, N. Y.), J. R. Cooper, J. H. Carter and C. S. Welch. Surgery 59(6):1079-1080, 1966.

Hepatectomized, splenectomized dogs received intrapelvic homologous transplants consisting of one-half a donor's liver implanted by side-to-side anastomosis between the residual of the donor's vena cava and the recipient's own, followed by end-to-end hepatic-iliac-arterial anastomosis, ligation of all hepatic veins at the vena cava, and cholecystojejunostomy or cholecystostomy after ligation of the common bile duct. Only 4 of 34 survived 24 hr., with blood supply limited to the hepatic artery. The survivors died on days 5, 6, 8 and 12 post-surgery. All recipients were treated with azathioprine, either pre- or postoperatively.

- 7234 BILE ACID METABOLISM. I. STUDIES ON THE MECHANISMS OF INTESTINAL TRANSPORT. (E.) Dietschy, J. M. (U. Texas Southwestern Med. Sch., Dallas), H. S. Salomon and M. D. Siperstein. J. Clin. Invest. 45(6):832-846, 1966.

In in vitro studies, the presence of active transport mechanisms for both conjugated and unconjugated bile salts was established in all segments of the distal half of the rat small intestine, with maximal values seen in the three terminal segments. The active carrier mechanism did not appear to distinguish between cholate and taurocholate, since active transport rates for the 2 were substantially identical. A similar substantial identity of passive ionic diffusion rates was also in evidence, given optimal pH values for the compound and process being studied. The nonionic diffusion rate for un-ionized cholic acid was also determined, as was the (presumably uniform) range of pH values within which cholic acid was the only compound capable of penetrating the intestinal mucosa. In correlative studies with everted gut sacs, it was found that apparent discrepancies in the transport of conjugated and unconjugated bile salts were an artifact of the pH gradient developed in this preparation, rather than an indication of differences in relative transport rates. Quantifications of active transport, passive ionic diffusion and passive nonionic diffusion in the rat small intestine in vivo confirmed that bile salt absorption could occur in each of these ways or via solvent drag, and that all 4 played a quantitatively significant role, the extent of involvement in the first 3 cases varying with the site (i.e., proximal to distal) and the compound (i.e., cholate, taurocholate or cholic acid), in response to pH differences and in accordance with a definable schema.

- 7235 CHIMERIC MICE WITH DONOR-TYPE LIVER CELLS. (E.) Hard, R. C., Jr. (Variety Club Heart Hosp., Minneapolis, Minn.) and B. Kullgren. Science 157(3720):349-352, 1966.

Newborn and weanling C₃H mice which had been lethally irradiated were made chimeric by inj. of massive numbers of (C₃H x T₆)F₁ spleen cells. This treatment allowed replacement of host hematopoietic tissue, giving rise to the persistent circulation

HEPATIC METABOLISM

of donor RBC and WBC. These F₁ spleen cells were admin. i.v. immediately after irradiation or i.p. in 1 or 2 doses within 24 hr. (with 1 booster 3 or 6 wk. later). Later, the mice were inj. s.c. with a 40% soln. of CCl₄ (0.1 ml/20 g body wt.) or were exposed to CCl₄ fumes for 2 min. to produce centrilobular necrosis of the liver. Colchicine (0.002 mg/g) was then inj. at the estimated peak of hepatic regeneration which follows necrosis. In these liver preparations, 93% of the mitotic figures were found in the parenchymal cells. In 98 of the 110 metaphases viewed the distinctive T₆ marker was seen (in both diploid and tetraploid cells), indicating that some of the liver parenchymal cells contained donor F₁ chromosomes. This is the first evidence, according to the authors, of uptake in vivo of functional nuclear material larger than nucleosides from nursing cells.

- 7236 GLUCOSE-6-PHOSPHATASE IN TUBULAR ENDOPLASMIC RETICULUM OF HEPATOCYTES. (E.) Rosen, S. I. (New York U., N. Y.), G. W. Kelly and V. B. Peters. Science 152(3720):352-354, 1966.

Glucose-6-phosphatase activity was found histochemically in the tubular endoplasmic reticulum, nuclear envelope, and ergastoplasm of liver cells from newborn (23-27 hr.) C₃H mice. Only those sections which were incubated in glucose-6-phosphate medium showed a lead reaction product after staining with lead citrate; sections incubated in fructose-6-phosphate, ribose-5-phosphate, fructose-1,6-diphosphate, adenosine monophosphate, β -glycerophosphate, and adenosine triphosphate did not. The identification of this activity in the tubular endoplasmic reticulum (which pervades the glycogen areas of these liver cells during glycogenolysis) further implicates this structure as the site of hepatic glycogenolysis.

- 7237 EXPERIMENTAL LIVER REGENERATION IN THE LIGHT OF MODERN RESEARCH. (Rum.) Vasilescu, V. (Inst. Med. Physiol., Bucharest, Rumania), G. Turcu, C. Dimoftache and G. Stoica. Fiziol. Norm. Pat. 12(2):143-150, 1966.

Two processes are involved in liver regeneration: hypertrophy (increase in cell size) and hyperplasia (increase in number of cells). The first requires a quantitative increase in cytoplasmic lipoprotein complexes under the control of RNA; the second, the accumulation of nuclear material, with resultant intensification of cell division. A parallelism between the biosynthesis of DNA and mitosis has been reported--and disputed. Various aspects of the phenomenon of liver regeneration are considered here--some based on reports gleaned from the literature, some on earlier publications of the authors, and some on their previously unpublished observations. Histophotometric determination of DNA in the visible range yielded lower curves at the 580 m μ peak for regenerating liver cells, reflecting greater absorption than in normal liver cells. Studies on C¹⁴-labeled glycine incorporation by normal and regenerating rat liver fractions (the latter from partially hepatectomized animals) showed substantially higher values in regenerating liver for all fractions, with max. incorporation by the nucleoprotein and mitochondrial fractions at 24 hr., and by the acid-soluble and lipid fractions, at 48 hr. In the initial days of liver regeneration, the hepatic level of free amino acids (glutamic acid, leucine, alanine, and methionine) was increased, as it was in the serum of hepatectomized animals. Earlier reports by others of increased incorporation of P³² into hepatic DNA and RNA in tumor-bearing animals were confirmed by the authors in radiochemical and autoradiographic studies, but no evidence was found for a further increase in incorporation of this precursor in hepatectomized tumor-bearing rats. Rational treatment of liver damage depends on the further exploration of the mechanism, neurohumoral and other, responsible for the stimulation and regulation of hepatic regeneration.

- 7238 STUDIES ON THE PROTEINS OF HUMAN BILE. I. IMMUNOLOGIC IDENTIFICATION OF SOME PROTEINS HITHERTO UNREPORTED IN HUMAN BILE. (Rum.) Stoica, G. (Inst. Intern. Med., Bucharest, Rumania) and A. Pappo. Stud. Cercet. Med. Intern. 7(1):29-34, 1966.

High-voltage agar gel microelectrophoresis and immunochemical technics (double two-dimensional diffusion on agar gel) were applied to the study of protein components in samples of human choledochhepatic bile derived by drainage from a patient who had undergone surgery for cholelithiasis. In addition to the fractions identified

HEPATIC METABOLISM

with a wide range of immune rabbit and horse sera, 2 other immunologically unidentified components were consistently observed with immunoelectrophoresis. The precipitation arc of one of them corresponded to that of alpha₁ anti-serum trypsin. On addition of rabbit antisera (against normal hepatic tissue and group O hemolysate) precipitation lines were obtained for 2 (and in one sample a 3rd) protein component not present in normal unconcentrated human serum.

- 7239 REGENERATION OF THE LIVER IN CATS. (Rus.) Bikmetov, G. N. (Inst. Exp. Biol., USSR Acad. Med. Sci., Moscow), L. M. Nebolsina and Z. V. Iakovleva. Biull. Eksp. Biol. Med. 61(3):89-92, 1966.

In experiments on cats of both sexes and variable age, ranging in wt. from 1,120 to 4,000 g, separate portions of the liver were resected from different lobes (I series), or two whole lobes (II series) were excised. In both series, the resected parts accounted for 30-33 per cent of the entire liver wt. The regenerating liver was studied in cats sacrificed on days 1, 2, 3, 4, 7 and 14 after surgery. It was found that the liver regeneration occurred at the expense of mitotic cell division. Series I did not show any restoration of removed parts of the organ, however, total liver wt. 35 days after surgery was the same as in controls of the same body wt. Mitoses were encountered mainly within the first four days. Max. mitotic index 72 hr. after surgery = 0.4%. Regeneration of the liver was accompanied by an increase in the wt. of the remaining parenchyma. At the same time, the relative wt. of the liver in young animals became equal to that in control animals on day 7 and in adult animals on day 14 after partial hepatectomy. Wt. of remaining hepatic part increased most intensively during the first 4 days. Microscopic studies of the liver of operated animals showed no essential changes with the exception of some cytoplasmic vacuolization of single hepatic cells during the early stages of regeneration (24-48 hr. after surgery), and the number of hepatic cells was the same in treated and controls. No mitosis was observed in controls.

- 7240 ELECTRON MICROSCOPY OF MONKEY LIVER AFTER EXPOSURE OF ANIMALS TO PURE OXYGEN ATMOSPHERE. (E.) Schaffner, F. (Mt. Sinai Hosp., New York, N. Y.) D. K. Roberts, F. L. Ginn and F. Ulvedal. Proc. Soc. Exp. Biol. Med. 121(4):1200-1203, 1966.

Electron microscopic examination of liver specimens taken from male monkeys (*Rhesus Macaca mulatta*) which were exposed to an atmosphere consisting of essentially 100% O₂ at a total pressure of 380 mm Hg for 2-22 days showed only minor, nonspecific changes. These changes appeared within the first day and were gone within 2 wk. after exposure. Such a time pattern indicates that the changes are probably an adaptive response rather than a sign of toxicity. The most significant and consistent change noted was an increase in smooth endoplasmic reticulum at the expense of the rough form and glycogen.

- 7241 OBSERVATIONS ON THE SUBCELLULAR ORGANIZATION OF HEPATIC PARENCHYMAL CELLS. I. GOLGI APPARATUS, CYTOSOMES, AND CYTOSEGREGOMES IN NORMAL CELLS. (E.) Ericsson, J. L. E. (Karolinska Inst. Sch. Med., Stockholm, Sweden) and W. H. Glinsmann. Lab. Invest. 15(4):750-761, 1966.

In normal rat liver parenchymal cells, the Golgi apparatus (which was usually located near a bile capillary) presented a "polarized" aspect, with a "forming" face close to the endoplasmic reticulum, and an "emitting" face containing Golgi vacuoles in the process of budding off from the cisternae of the Golgi bodies. Transitional organelles between the Golgi vacuoles and the cytosomes were seen, indicating that many cytosomes are derived from the Golgi membranes. Acid phosphatase was noted in some of these vacuoles, which seemed to represent "primary" lysosomes. Other cytosomes seemed to arise from the degradation of cytoplasmic constituents within the cytosegresomes ("autophagic vacuoles"). Acid phosphatase was not seen in the Golgi cisternae in this study, but was demonstrable in vacuoles budding off these cisternae. It is suggested that enzymes of the acid hydrolase group are synthesized on the ribosomes, then transferred to the Golgi cisternae via the endoplasmic reticulum, and then to the Golgi vacuoles which eventually form cytosomes. In the case of cytosegresome-derived cytosomes, the cisternae of Golgi-associated endoplasmic reticulum wrapping around the organelles to be segregated, may be the source of the enzymes.

HEPATIC METABOLISM

- 7242 THE UPTAKE OF CONJUGATED BILIRUBIN BY RAT LIVER. (E.) Hargreaves, T. (St. George's Hosp., London, S.W.1) and V. Price. Biochem. Pharmacol. 15(5):657-667, 1966.

Rat liver or kidney slices incubated for 1 hr. in a phosphate-bicarbonate soln. containing conjugated bilirubin (150 μ g) showed an increased uptake of the pigment, which was greater in liver than kidney tissue; however, uptake was greatest (and equal) in denatured kidney or liver. In normal liver tissue the uptake increased with time; in normal kidney tissue, it decreased after an initial peak. In all tissue types, the uptake diminished with diminishing temperatures and was unaffected by pH changes within the range of 6.5-8.0. With heat-denatured tissue, the uptake increased as the temperature of denaturation rose. Albumin or mercuric significantly retarded the uptake of conjugated bilirubin by liver tissue; sodium fluoride, arsenite, iodoacetate, cyanide, dinitrophenol, or ouabain had no effect.

- 7243 STUDIES OF THE MECHANISM OF ACTION OF AN ORGAN-SPECIFIC LIVER SUBSTRATE. (Ger.) Hammerl, H. (Wilhelminen Hosp., Vienna, Austria), O. Pichler and M. Studlar. Arzneimittelforschung 16(3):438-440, 1966.

An organ-specific substrate derived from young, viable hepatic cells and combined with bacterial heptane ("Hepa-Kombun") was admin. s.c. to 10 adult, male subjects who gave no evidence of functional or organic liver disorders. The subjects acted as their own controls. Thirty min. post-admin., free fatty acids in blood plasma were reduced by 30% and initial levels had not been entirely regained at the end of 3 hr. A simultaneous increase of serum glucose was not at a level of statistical significance; it normalized spontaneously within 3 hr. The absolute count of eosinophils was diminished significantly within 30 min. and recovered slowly to reach normal levels in 3 hr. It is concluded that the compound accelerated oxidation of fatty acids in the liver and speculated that the decrease of free fatty acid conc. in blood plasma may also indicate a primary increase of intrahepatic glycolysis.

- 7244 LIVER BLOOD FLOW MEASURED BY PORTAL VENOUS AND HEPATIC ARTERIAL ROUTES WITH Kr⁸⁵. (E.) Hollenberg, M. (Cornell U. Coll. Med., New York, N. Y.) and J. Dougherty. Am. J. Physiol. 210(5):926-932, 1966.

The portal veins in 22 dogs used for acute experiments and in 4 dogs used for serial blood flow measurements were cannulated near the hilum of the liver. In the acute dogs a second catheter was implanted in the common hepatic artery near its origin from the celiac artery and proximal to the origin of the gastro-pancreatico-duodenal artery. Blood flow through the liver was determined by use of external scintillation counting over the liver after the rapid inj. of krypton⁸⁵ into the portal vein and after inj. 5 min. later into the hepatic artery. Krypton derived flows varied linearly with pumped, metered portal vein flow over a wide range of flow rates in the control state, during norepinephrine infusion, and after hemorrhage. Mean liver flow rates (measured by the portal venous route) in trained, conscious dogs over a 3-wk. period ranged from 150 to 210 ml/100 g per min. A mixture of the portal venous and hepatic arterial streams was demonstrated in acute experiments in which first the hepatic artery and then the portal vein was clamped. However, the different liver flow rates measured by these two routes suggest that these streams perfuse slightly different through related vascular beds. Some portal venous channels exist which share no common capillary pathways with the hepatic arterial stream. These probably serve as high-flow, preferential, thoroughfare channels.

- 7245 EFFECTS OF COMMON BILE DUCT LIGATION ON COMPENSATING HEPATIC HYPERTROPHY IN PARABIOTIC RATS. (Fr.) Binet, L. (U. Paris Sch. Med., Sorbonne) and R. Molimard. C. R. Acad. Sci. (Paris) 262(1)(Ser. D):139-142, 1966.

Parabiosis was maintained for 8 days in 20 Wistar rats by establishment of communication between their peritoneal cavities; right parabionts were subjected to a step partial hepatectomy, 6 were in combination with ligation of the common bile duct. No inhibitory effect on compensating hepatic hypertrophy was observed in rats with ligated common bile ducts as compared to controls. Under the experimental conditions described, the livers of their partners showed no compensating hypertrophic response. Data failed to indicate the presence of a humoral factor in parabiotic rats which regulates compensating hypertrophy of the liver.

HEPATIC METABOLISM

- 7246 SYNTHESIS OF CLOTTING FACTORS BY THE ISOLATED PERFUSED RAT LIVER. (E.)
Olson, J. P. (U. Rochester Med. Ctr., N. Y.), L. E. Miller and S. B. Troup.
J. Clin. Invest. 45(5):690-701, 1966.

Direct evidence of hepatic synthesis of prothrombin, Factors V, VII and X was obtained in an isolated rat liver preparation. Clotting factor assays were performed over a 7-hr. period on the perfusate of defibrinated rat serum which contained washed rat erythrocytes. In this time period, the prothrombin activity increased from control of less than 2% to 10-15%; Factor X activity increased from less than 2% to 20-40%; and Factor V activity increased from 10-15% to 30-50%. Treatment of donor animals with Coumadin (Warfarin sodium) inhibited prothrombin and Factor VII but not Factor activity and this effect of Coumadin was antagonized by the addition of vitamin K₁ to the perfusate. The addition of puromycin to the perfusion fluid decreased the activity of prothrombin, Factor V and X but not of Factor VII, during the last 4 hr. of the experiment. Inhibition of activity of prothrombin and Factor X, but not of Factor V by Coumadin and puromycin, was antagonized by vitamin K. Addition of puromycin, Coumadin or vitamin K directly to the rat plasma did not alter the activity of the clotting factors. The data provided direct evidence for liver synthesis of prothrombin and Factors V, VII and X and suggested that Coumadin and vitamin K act between ribosomal synthesis and the appearance of active prothrombin, Factor VII and Factor X.

- 7247 EXPERIMENTAL HEPATIC REGENERATION IN THE RAT. I. LIGATION OF THE SPLENIC VEIN. (It.) Cavallotti, C. (U. Rome) and N. Garcea. Boll. Soc. Ital. Biol. Sper. 42(2):82-85, 1966.

Hepatic regeneration was studied in 21 Wistar rats (wt. 200 g) subjected to partial hepatectomy (65%; Crandall-Drabkin technic) and double ligation of the splenic vein at its entry into the portal vein (Sielberg technic). Animals subjected to this technic regained 66.8% of initial liver wt. by day 2 and 90% by day 10. Results are similar to those reported previously by the authors for hepatectomy and splenectomy. Hepatectomy and ligation of the splenic vein were better tolerated than hepatectomy and splenectomy, as evidenced by higher total body wt. in animals of the former group. Mortality was nil in the former group and 40% in the latter group.

- 7248 MITOTIC CHANGES IN RAT LIVER AFTER INTRAPERITONEAL PAPAIN PROTEASE. (E.)
Kambara, T. (Kumamoto U. Sch. Med., Japan) and Y. Nohara. Arch. Path. (Chicago) 81(6):525-530, 1966.

Crystalline papain protease at 5 different conc. levels of caseinolytic activity was given i.p. to 25 rats (5/group) and the mitotic figures from randomly selected microscopic fields of liver, kidney, small intestine, heart and adrenal were counted at 48 hr. after the inj. In the liver, the av. number of mitoses/100,000 cells was 10 in the untreated rats and increased from 45 to 579 as the papain activity increased. There were no pathological changes in the liver and the mitotic figures were normal; all stages of the mitotic cycle were present, and the figures were diffusely distributed throughout the liver lobules indicating that the changes were produced by the enzyme action rather than as a compensatory mechanism from damaged or necrotic tissue. The mitotic activity of the kidney was increased from a control of 4.8/5000 to 24.4/5000 cells and that of the heart from a control of 0/50 to 2/50 optical fields after the injection of papain; however there was no change in the mitosis of the small intestine or adrenal gland.

- 7249 PROTEIN BINDING OF BILIRUBIN AND SULFOBROMOPHTHALEIN. (Ger.) Scholtan, W. (Farbenfabriken Bayer AG, Leverkusen, Germany) and C. Gloxhuber. Arzneimittelforschung 16(4):520-528, 1966.

The protein binding of bilirubin (I), I diglucuronide, sulfobromophthalein (II), and II-glutathione was studied *in vitro* by ultracentrifugation and dialysis. I and II were bound almost completely (98%) by serum protein bodies; protein binding of their resp. metabolites was slightly less. There was a linear relationship between the logarithm of the conc. of bound pigment and the logarithm of the conc. of free pigment. The interaction between albumin molecules and I or II was subject to the law of mass action and was characterized by a binding constant, free energy, and the number of binding groups (10/albumin molecule for I and 16 for II). In the pigment-

HEPATIC METABOLISM

containing albumin soln., pigment binding was linked with an alteration in the tertiary structure of the albumin molecule; the affinities of the binding groups differed from one another. I, II and their metabolites were displaced from the protein bond by the addition of 1% dried bile, but the penicillin derivative Dicloxacillin was inactive in this respect.

- 250 IN VIVO DEIODINATION OF ^{131} -ROSE BENGAL AFTER CARBON TETRACHLORIDE ADMINISTRATION IN RATS. (Ger.) Bergner, H. (Humboldt U., Berlin). Acta Biol. Med. German. 16(3):294-299, 1966.

In rats not treated with CCl_4 , the deiodination of ^{131} -rose bengal was not affected by fasting; in rats fed a normal diet and treated with CCl_4 (0.1 ml/100 g i.p.) every other day (3 inj.), deiodination of the dye also remained unchanged. In rats treated with a single inj. of CCl_4 and fed a normal diet, deiodination increased to 243% of the control rate after 1 day, but returned to control levels after 5 days. Admin. of CCl_4 to fasted rats resulted in a significant but smaller increase in the deiodination rate (129% after 1 day). In rats fed a normal diet for 4 days before CCl_4 admin., the deiodination rate after 1 and 3 days was 119% and 116% of control values, resp., if the normal diet was continued after CCl_4 admin., compared to 104% and 141% of control values, resp., in animals given a protein-free diet after treatment with CCl_4 . In rats admin. a protein-free diet for 6 days, followed by 3 inj. of CCl_4 on alternate days, deiodination of the dye was retarded significantly.

- 251 BIOCHEMICAL STUDIES WITH PRESERVED TRANSPLANTED CANINE LIVER. (E.) Brown, H. (Harvard Med. Sch., Boston, Mass.), J. Patel, D. W. Blair and M. E. Brown. J.A.M.A. 196(9):775-779, 1966.

A technic is described for preserving dog liver by partial dehydration and cooling. Oxygen consumption fell by about 50% after 24 hr. of storage (in glycerol or dimethyl sulfoxide at -6°C) and by about 90% after 4-5 days; however, even after 4 or 5 days of storage, heterotopically transplanted livers showed some temporary function. Urea cycle enzyme activity (carbamyl phosphate synthetase, ornithine transcarbamylase, arginase, and argininosuccinase) was normal after as much as 45 days of storage. In dogs with orthotopic liver transplants, sulfobromophthalein retention after 45 and 60 min. was about 50% and 33%, resp.; glucose tolerance tests were abnormal. The failure of these transplants is attributed to hepatic outflow block and clostridial infection of the transplants, both of which are characteristic of canine liver.

- 252 EARLY CHANGES IN LIVER CYTOPLASMIC RNA OF HYDROCORTISONE-TREATED RATS. (E.) Finkel, R. M. (Harvard Med. Sch., Boston, Mass.), E. C. Henshaw and H. H. Hiatt. Molec. Pharmacol. 2(3):221-226, 1966.

Cytoplasmic RNA metabolism was studied by C^{14} -orotic acid labeling in liver tissue from adrenalectomized rats, during the period following hydrocortisone admin. that preceded the steroid-induced increases in several liver enzymes. Labeling of the 45S cytoplasmic particles was greatly increased 2 hr. after hydrocortisone treatment; these particles may carry newly synthesized messenger RNA from the nucleus to the cytoplasmic ribosomes. Max. tryptophan pyrrolase synthesis occurred after 3.5 hr., which was just after the 45S particles reached max. activity and the 80S ribosomes were minimal. It is suggested that cortisol stabilizes the polyribosomes on the membranes, preventing their disruption into nonfunctional 80S ribosomes; the steroid may also stimulate the formation of new membrane-bound polyribosomes from the pool of free 80S particles, possibly by making available more messenger RNA on the 45S particles. The newly synthesized RNA of the 45S particles may also contain ribosomal RNA.

- 253 EXPERIENCES IN EX VIVO PERFUSION OF THE LIVER. (E.) Darin, J. C. (Marquette U. Sch. Med., Milwaukee, Wis.). Am. J. Surg. 111(6):870-872, 1966.

Ex vivo hepatic perfusion was studied in goats and human cadavers. In the goat, portal vein flows up to 1,800 ml/min. were maintained in perfusions up to 6 hr.; maintenance of hepatic artery flow, however, was most difficult. In the liver in man, portal vein and hepatic artery flows were easily maintained during the entire

HEPATIC METABOLISM

period of perfusion. Bile production in the goat varied from 2-8 ml/hr. and became progressively less as the perfusion continued; an av. of 5 ml/hr. was produced in the human subject. Intermittent negative pressure could not be used in either system due to the creation of outflow block. In the human subject, low molecular wt. dextran had no effect on either inflow tract. Results indicate that the perfused liver of the goat will function, but it is not an entirely satisfactory model for perfusion because of the low hemoglobin content (7.5 g), low hematocrit (20%), and fragility of goat's blood. The *ex vivo* perfused liver in human cadavers functions, and its use in an extracorporeal hepatic support system should be feasible.

- 7254 STUDY OF CLOTTING FACTORS IN LIVER HOMOTRANSPLANTATION. (E.) Stremple, J. F. (Marquette U. Sch. Med., Milwaukee, Wis.), C. V. Hussey and E. H. Ellison. *Am. J. Surg.* 111(6):826-867, 1966.

Coagulation factors were measured in 12 adult mongrel dogs receiving donor livers; animals were anesthetized with Pentothal sodium and maintained with ether anesthesia. Controls received the same anesthetic treatment without an operative procedure. Six of the 12 animals with an auxiliary liver manifested a hemorrhagic diathesis as evidenced by incoagulability and uncontrollable hemorrhage from vascular anastomoses which had been previously sealed. Measurable levels of endogenous heparin were seen in 6 of 12 animals after liver allografts. Animals with bleeding showed a decrease in fibrinogen, platelets, and Factor V of 83, 43, and 80%, resp.; prothrombin time was increased 2-6 times; heparin was seen in 5 but fibrolysin in none. Removal of the host liver had no influence on the appearance of a bleeding diathesis, active fibrinolysin, or endogenous heparin. The appearance of heparin 3 days after a liver allograft without manifestation of excessive bleeding or decrease in fibrinogen or platelets suggests that endogenous heparin may be released primarily in an immune response. This immune reaction alters clotting factors, and may contribute to a hemorrhagic diathesis.

- 7255 CONTINUOUS PERFUSION OF RAT LIVER UNDERGOING AUTOLYSIS. (Ger.) Bohley, P. (U. Halle, Germany), R. Kleine, M. Frohne, H. Kirschke, J. Langner and H. Hanson. *Hoppe Seyler Zschr. Physiol. Chem.* 344(1-3):55-74, 1966.

Continuous perfusion for 5 days of rat liver with sterile Ringer soln. free of Ca and Mg, in the absence of oxygen, resulted in the loss of almost two-thirds the total protein content, although only approximately 8% was transformed into degradation products which were soluble in trichloroacetic acid. The release of soluble hyaloplasmic enzymes was virtually complete within 4 hr., but only small amounts of microsomal enzymes appeared, and then only after hr. 9. Small quantities of lysosomal enzymes were released during the first 8 hr., with approx. 40% released between hr. 9 and 24. Autoproteolysis had already ended in some livers still containing 40% of the total lysosomal enzyme content after 24 hr., but was undiminished in others which had lost as much as 90% of their original content of lysosomal cathepsin. Autolytic destruction of individual cells could not be demonstrated after hr. 3.

- 7256 SPECTROPHOTOMETRIC ASSAY OF THE LIVER ENZYME THAT CATALYZES SULFOBROMOPHTHALEIN-GLUTATHIONE CONJUGATION. (E.) Goldstein, J. (U. Texas South-west. Sch. Med., Dallas) and B. Combes. *J. Lab. Clin. Med.* 67(5):863-872, 1966.

A new spectrophotometric method for measuring the activity of the enzyme that conjugates sulfobromophthalein with glutathione has been developed. This rapidly performed assay is based on the observation that sulfobromophthalein-glutathione has a greater optical density than equimolar quantities of free sulfobromophthalein at wave lengths less than 500 mμ. When appropriate quantities of sulfobromophthalein and glutathione are incubated at 37°C, pH 8.0, a linear increase in optical density due to nonenzymatic formation of sulfobromophthalein-glutathione occurs. The additional rate of increase in optical density when liver enzyme is present serves as a means of measuring the activity of this enzyme. The observation that the rate of sulfobromophthalein conjugation *in vitro* is significantly affected by changes in pH in the physiological range indicates that intracellular pH changes may exert an important control on the rate of sulfobromophthalein conjugation *in vitro*. In a comparison of results obtained with previous assay methods, av. fetal and 3-day-old

HEPATIC METABOLISM

neonatal liver activity was 9.2 and 18.6%, resp., with the new method as compared to 11.7 and 23.4%, resp., with the older assay methods. (See also 7257.)

- 7257 THE EFFECT OF STEROIDS ON THE ACTIVITY OF THE ENZYME THAT CATALYZES SULFO-BROMOPHTHALEIN-GLUTATHIONE CONJUGATION. (E.) Goldstein, J. (U. Texas Southwest. Sch. Med., Dallas) and B. Combes. J. Lab. Clin. Med. 67(5): 830-835, 1966.

The effect of various steroids on sulfobromophthalein-glutathione conjugating enzyme activity was determined in vitro using a new spectrophotometric assay. Steroids (C₁₈, C₁₉, C₂₁, and 17 α -alkylated anabolic) were added to the in vitro system in a final conc. of 5 μ g/ml, i.e. considerably in excess of expected in vivo levels. Only 17 α -ethyl-19-nortestosterone (Nilevar) enhanced enzyme activity significantly (60% at 5 μ g/ml). Several other 17 α -alkylated anabolic steroids had virtually no effect on sulfobromophthalein conjugation in vitro. Other steroids, including estradiol, estriol, progesterone, testosterone and cortisone, had either no effect or only mild stimulating or inhibiting activity at the above conc. Results suggest that most steroids, even in pharmacological doses, have little if any effect on the enzyme that catalyzes sulfobromophthalein-glutathione conjugation. Direct evidence is also provided that impaired sulfobromophthalein excretion observed with estrogens and anabolic steroids is due to interference with hepatic sulfobromophthalein transport mechanisms. (See also 7256.)

- 7258 METABOLISM OF Cu⁶⁴-LABELED COPPER BY THE ISOLATED RAT LIVER. (E.) Owen, C. A., Jr. (Mayo Clin., Rochester, Minn.) and J. B. Hazelrig. Am. J. Physiol. 210(5):1059-1064, 1966.

While, adult male rats (Sprague-Dawley strain) were used in all studies. Liver perfusions were carried out by a modification of the technic of Brauer et al. To minimize the effects of vasoconstrictive substances that appear in the perfusate, one liver was employed for 1 hr. and then replaced by a second liver in which the study was carried out. Labeled (Cu⁶⁴) cupric acetate was diluted in heparinized rat plasma and was slowly added to the reservoir for at least 10 min. before the second liver was inserted. These procedures tended to minimize erythrocyte uptake of the Cu⁶⁴. When the disposition of Cu⁶⁴ by isolated, perfused rat livers was compared with that by intact rats, hepatic uptake and biliary excretion of the Cu⁶⁴ and emergence of labeled ceruloplasmin in the blood were comparable. It was concluded that, in the rat, ceruloplasmin is synthesized primarily, or perhaps only, by the liver.

- 7259 THOROTRAST INHIBITION OF AMYLASE SYNTHESIS BY THE ISOLATED, PERFUSED RAT LIVER. (E.) Hiatt, N. (Cedars-Sinai Med. Ctr., Los Angeles, Cal.), G. M. Coverdale and G. Bonorris. Proc. Soc. Exp. Biol. Med. 121(4):1122-1124, 1966.

The reticuloendothelial system in the experimental group of rats (Slonaker-Addis strain) was blocked by i.v. inj. of Thorotrast (25% soln., 3 ml/kg). The liver was removed and was perfused with 100-120 ml of heparinized rat blood diluted to 150 ml with Ringer's soln. When the perfusion fluid was tested over a period of up to 3 hr., it was seen that the isolated, perfused livers from normal rats synthesized amylase and released it into the perfusion medium. The isolated, perfused livers from rats with Thorotrast blockade of the reticuloendothelial system did not synthesize amylase. It is not clear why Thorotrast blockade of the reticuloendothelial system inhibits the release of amylase into the perfusion medium.

- 7260 INFLUENCE OF OROTIC ACID ON THE HEPATIC PARENCHYMA. VIII. CHANGES OF THE LOCALIZATION OF ACID PHOSPHATASE AND AS-ESTERASE IN THE LIVER AFTER APPLICATION OF OROTIC ACID AND VITAMIN B₁₂. (E.) Křiška, M. (Charles U., Plzen, Czech.), S. Reiniš and J. Šůva. Acta Histochem. (Jena) 23(1-4): 80-85, 1966.

Histochemical technics were employed to follow changes of acid phosphatase and non-specific acetylcholine-esterases in the livers of rats fed for 21 days a balanced diet (controls) or the diet plus orotic acid and/or vitamin B₁₂. In the livers of controls, non-specific esterases were present in all cells of the central part of

HEPATIC METABOLISM

the lobule. With orotic acid only, the non-specific esterases were decreased in some liver cells, while the staining was deeper in other cells. Addition of high doses of vitamin B₁₂ (500 µg/kg every other day) prevented this change although the liver structure was still not completely normal. In normal livers, acid phosphatase was localized in the cytoplasm of the surface of cells. With the feeding of orotic acid alone, the acid phosphatase activity was intense throughout the entire cytoplasm; the nucleus showed no activity. Simultaneous feeding of high doses of vitamin B₁₂ led to some islands of normal cells; small doses of the vitamin were ineffective.

- 7261 SEROTONIN METABOLISM IN THE ISOLATED PERFUSED CANINE LIVER. (E.) Moore, T. C. (U. Kentucky Coll. Med., Lexington) and B. Eiseman. Surgery 59(5): 765-769, 1966.

Hepatic metabolism of serotonin was investigated by rapid serotonin loading of the sterile isolated canine liver perfusion system. A total of 42 serotonin loadings (5, 10, and 20 mg) were carried out in 15 liver and 7 control (with exclusion of the liver) perfusions. Conc. of serotonin and 5-hydroxyindoleacetic acid were determined (fluorimetric assay method) before and after loading. Serotonin was rapidly cleared from the liver perfusion system but remained at persistently high levels in control perfusions. The max. post-loading conc. of serotonin in liver and control perfusion indicated that from 65 to 85% of the serotonin was cleared in initial passage through the liver. Clearance of serotonin by perfused liver was markedly impaired by reduction in hepatic blood flow below 500 ml/min. The efficiency and rapidity with which large amounts of serotonin were cleared from the perfusion system suggest a sizable hepatic reserve for serotonin metabolic degradation. The assumption that the clearance of serotonin from the perfusion system was by metabolic breakdown was confirmed by the demonstration of a progressive increase in 5-hydroxyindoleacetic acid levels after loading. No elevation in 5-hydroxyindoleacetic levels was observed in control loadings with the liver excluded from the system.

- 7262 EFFECTS OF A SYNTHETIC ANABOLIC AGENT ON HEPATIC FUNCTION. (E.) Ticktin, H. E. (George Washington U. Med., Washington, D. C.) and H. J. Zimmerman. Am. J. Med. Sci. 251(6):674-684, 1966.

The totally synthetic C-17 alkylated anabolic agent dl-13,17a-diethyl-17-hydroxygon-4-en-3-one (norbolethone) was admin. to 24 ambulatory, hospitalized patients with minimal tuberculosis (p.o., 1.25-2.5 mg/day for 2-18 wk.). The 5 patients admin. 2.5 mg/day were compared to 6 others admin. equivalent anabolic doses (8 mg/day) of methandrostenolone, in a double-blind study; both groups of patients were also treated with p-aminosalicylic acid and isoniazid. Larger doses of norbolethone (5-20 mg/day for 2-4 wk.) were admin. to 17 healthy volunteers. Sulfobromophthalein excretion was impaired and serum glutamic-oxalacetic transaminase was mildly increased in proportion to the dosage in 31 and 40 cases, resp. Serum bilirubin was slightly elevated in 20% (11 of 52 cases) of the group, but other liver function tests (thymol turbidity, cephalin flocculation, and alkaline phosphatase) remained normal throughout the study. The effects of norbolethone on liver function tended to level off after 2-3 wk. in some patients. Liver function tests tended to return to normal shortly after treatment was stopped; wt. gain, which was constant throughout the study, was proportional to the dosage, and at some doses the wt. continued to increase slightly after treatment was stopped. The effects of equivalent doses of methandrostenolone on liver function were substantially the same, but the av. cumulative wt. gain was greater with norbolethone. Intermittent admin. of large doses of norbolethone (7.5 mg, 2 doses/wk.) caused a greater wt. gain with less liver dysfunction than the equivalent weekly dose admin. daily; only 4 of 16 patients treated in this way showed any liver dysfunction.

- 7263 FURTHER CONTRIBUTION TO THE KNOWLEDGE OF LIVER INNERVATION IN MAN. (Ger.) Hadžiselimović, H. (U. Sarajevo, Yugoslavia) and N. Gluhbegović. Zschr. Anat. Entwicklungsgesch. 125(1):64-66, 1966.

The course of the nerve arising from the medial nerve plexus of the right adrenal and extending to the right hepatic lobe was studied in 70 unselected human autopsy

HEPATIC METABOLISM

specimens. This nerve branch passes between the inferior vena cava and the pars descendens of the duodenum, to reach the under surface of the right hepatic lobe to the right of the lobus and porta hepatis, where it forms two branches. In 63 cases, these branches extended to the capsule and the parenchyma; in the other 7 cases they extended directly to the parenchyma. The parenchymal nerves form a plexus which (in 50% of the cases studied) formed an anastomosis with the intra-hepatic branches of the arteria hepatica propria.

- 7264 EFFECT OF HUNGER AND PROTEIN FEEDING IN PREGNANT RATS ON THE METABOLISM OF FETAL LIVER. (Ger.) Theile, H. (U. Leipzig, Germany) and D. Steffenhagen. *Paediat. Grenzgeb.* 5(2):131-140, 1966.

The activities of aldolase, glutamic-oxalacetic and glutamic-pyruvic transaminases, and of lactic, malic, and succinic dehydrogenases, as well as oxygen consumption, were studied in adult female rats and their newborn offspring after 72-84 hr. of fasting or 9-11 days of protein feeding just prior to delivery. After fasting, aldolase, malic dehydrogenase, and succinic dehydrogenase activities decreased, and oxygen consumption with a pyruvate-fumarate substrate increased, in the livers of the females, but there was no change in the metabolism of the fetal liver. After protein feeding, the adult livers showed a decreased nitrogen content, decreased transaminase activity, and a decrease in oxygen consumption. In fetal liver, the activities of aldolase and both transaminases decreased, with a similar reduction in oxygen consumption using glucose or pyruvate-fumarate as a substrate.

- 7265 QUESTION OF γ -GLOBULIN FORMATION IN THE NORMAL HUMAN LIVER. (Ger.) Lunzenauer, K. (Humboldt U., Berlin), E. Seidler and I. Biester. *Frankfurt. Zschr. Path.* 75(2):158-163, 1966.

Liver slices obtained within 10 hr. after death from 20 patients (age 40-75 yr.) who had no histories of hepatic disease, infection, or immunological disorders, were treated with rabbit anti-human γ -globulin and stained for examination by fluorescence microscopy. Control preparations (from the same patients) showed bright green fluorescence in the elastic and collagen fibers and the reticulohistiocytic and plasma cell elements of the spleen and (to a lesser extent) lymph nodes. The number of fluorescent cells in these tissues tended to decrease with age. Very few fluorescent cells were seen in the liver, except in 3 patients who died of myocardial infarction (2) or carcinoma without liver metastases (1). Most of the fluorescent cells were seen near the sinusoids and resembled Kupffer cells. The periportal areas also contained a few fluorescent cells resembling plasma cells, with very occasional lymphocyte types, which were as basophilic as the Kupffer cells after hematoxylin-eosin staining. It is concluded that the Kupffer and plasma cells are potential sites of γ -globulin synthesis in the liver.

- 7266 EFFECTS OF FAT MOBILIZATION ON LIVER ACETATE METABOLISM. (E.) Bewsher, P. D. (Indiana U. Sch. Med., Indianapolis), M. E. Tarrant and J. Ashmore. *Diabetes* 15(5):346-350, 1966.

In rats, treatment with adrenergic blocking agent dichloroisoproterenol (50 mg/kg i.p.) had no effect upon blood glucose levels, but caused an increase of about 50% in total liver lipids and liver ketones; plasma free fatty acids and blood ketones almost doubled, while liver fatty acid synthesis from acetate fell by 75%. Addition of insulin (5 U s.c.) 1 hr. before sacrifice produced hypoglycemia and caused a reduction of plasma free fatty acids to normal levels, but did not affect blood ketones or acetate incorporation into fatty acids by the liver. It is concluded that lipid mobilization is sufficient to produce changes in liver metabolism (possibly due to a direct effect of accumulation of lipids or acyl-coenzyme A in the tissue) resembling those seen in diabetes mellitus.

- 7267 THE EFFECTS OF THYROXINE ON THE PATTERN OF FATTY ACID SYNTHESIS IN RAT LIVER. (E.) Gompertz, D. (U. London) and A. L. Greenbaum. *Biochim. Biophys. Acta* 116(3):441-459, 1966.

After 4 days of treatment with L-thyroxine (s.c.), acetate incorporation into stearic acid was highest at lower, more physiological doses (10 or 100 μ g/day) and fell off at 500 μ g/day; octadecenoic acid synthesis increased with increasing dosage.

HEPATIC METABOLISM

Palmitic acid synthesis was stimulated 70% at the lowest dose, but slightly inhibited at the highest. Acetate incorporation into these 3 acids accounted for about 90% of total lipogenesis. Total lipogenesis was stimulated by 90% at the lowest dose; at 500 µg/day, palmitic acid synthesis was inhibited but the synthesis of the other 2 fatty acids was stimulated, which resulted in a negligible change (5% increase) in total lipogenesis at this dose, despite great changes in the pattern of incorporation. Synthesis of the 20-carbon polyunsaturated fatty acids was increased at all doses, but the overall rate of acetate incorporation was small. The increased octadecenoic synthesis seemed to be associated with an increased desaturation of stearic acid in liver slices and in microsomal systems; stearyl-coenzyme A desaturase activity was also increased. Studies of the effects of L-thyroxine (500 µg/day) on oleic acid synthesis in the livers of animals made diabetic with alloxan (19 mg/100 g i.p.) suggested that thyroxine and insulin both control the activity of the stearic acid desaturation mechanism, and that thyroxine can replace this insulin action in the diabetic liver.

- 7268 ABSENCE OF INCREASED [^{14}C] OROTIC ACID UPTAKE IN PERFUSED LIVER REMNANTS. (E.) Gordon, A. H. (Nat. Inst. Med. Res., London) and G. S. Hodgson. *Biochim. Biophys. Acta* 119(2):427-428, 1966.

After 4 hr. of perfusion *in vivo*, the liver remnants of rats that had undergone 67% hepatectomy showed a 2-fold increase in the incorporation of C^{14} -orotic acid into acid-insoluble RNA. If either the whole liver or the liver remnant was perfused with rat serum *in vitro* for 4 hr., however, C^{14} -orotic acid uptake remained unchanged. It is suggested that humoral and/or nervous factors are involved in the early response of RNA synthesis after partial hepatectomy.

- 7269 THE EFFECT OF DIET ON THE COMPOSITIONS OF THE TRIGLYCERIDES AND UNESTERIFIED FATTY ACIDS ISOLATED FROM THE PLASMA, LIVER AND ADIPOSE TISSUES OF RABBITS. (E.) Moore, J. H. (Nat. Inst. Res. Dairy, Shinfield, Reading, England) and D. L. Williams. *Brit. J. Nutr.* 20(1):79-93, 1966.

Various groups of rabbits were fed (1) a commercial rabbit diet, (2) a low-fat basal diet or this diet with an inadequate supplementation of corn oil and wheat starch, or (3) the low-fat diet supplemented with corn oil and/or butterfat or corn oil plus wheat starch. Rabbits were given the diets for 38 wk. The effects of the different diets on the composition of the unesterified fatty acids in the plasma were very similar to the effects of the diets on the fatty acid composition of the plasma triglycerides. However, in the plasma unesterified fatty acids, the conc. of stearic acid was consistently higher and the conc. of linoleic acid was consistently lower than in the plasma triglycerides. In the 2 groups given low-fat diets the fatty acid composition of the liver triglycerides was almost identical with that of the plasma triglycerides. In each of the 6 groups of rabbits, the composition of the unesterified fatty acids in the plasma was identical with that of the unesterified fatty acids in the adipose tissues. In the unesterified fatty acids of the liver the conc. of linoleic and arachidonic acids were consistently greater and the conc. of myristic, palmitic and palmitoleic acids were consistently less than the corresponding conc. of these acids in the unesterified fatty acids of the plasma and adipose tissue.

- 7270 RESPONSE OF THE MESENTERIC VESSELS TO OCCLUSION OF THE PORTAL VEIN. (Ger.) Stogoi, G. (U. Bologna, Italy) and G. C. Cavalli. *Zschr. Gastroent.* 4(1):5-14, 1966.

Several groups of rats were submitted to partial or complete occlusion of the portal vein for varying periods of time before sacrifice, either continuously or by termination of the condition followed by a second intervention after periods of 1-2 mo. The animals were also examined at various intervals by splenoportography and splenomanometry. In all animals both the overall volume and the internal pressure of the spleen were increased, although a significant correlation between intrasplenic pressure and that in the collateral vessels could not be established. Vascular changes included a significant increase of muscle cells and elastic fibers, which was very marked in the small intestine and especially marked in the colon. Although neither of these changes occurred uniformly, they extended as far as the site of the ligation.

HEPATIC METABOLISM

and also occurred in the arteries, especially those of the submucosa and serosa. They were accompanied by muscle formations which appeared to regulate the flow. No uniform relationship was established between circulatory changes and alterations of vascular structure. Circulation grew progressively worse in the villi, as partial or total occlusion was prolonged. It is concluded that, although the changed hemodynamic situation can be tolerated at first, because of compensatory vascular changes, prolongation of the situation leads to exhaustion of the system's ability to adapt and thus to the onset of decompensation.

- 7271 THE FATTY ACID CONTENT OF HEPATIC LIPIDS OF RATS IN A STATE OF INANITION. (Ger.) Ritzel, G. (U. Basel, Switzerland) and K. Bernhard. Zschr. Ernaehrungswiss. 6(4):248-252, 1966.

Inadequate feeding or total starvation of rats, prolonged until death or a wt. loss of 10-50%, failed to induce statistically significant changes in the fatty-acid content of the hepatic lipids.

- 7272 ENZYME-HISTIOGRAMS AND PATTERNS OF ENZYME ACTIVITY IN RAT LIVER. DEMONSTRATION OF PYRIDINE NUCLEOTIDE-SPECIFIC DEHYDROGENASES IN GEL-FILM STUDIES. (Ger.) Pette, D. (U. Munich, Germany) and H. Brandau. Enzym. Biol. Clin. (Basel) 6(2):79-122, 1966.

A new gel-film technic made it possible to demonstrate 3 groups of pyridine nucleotide-linked dehydrogenases in rat liver, as well as their primary localizations. One group showed a uniform distribution of activity throughout the hepatic lobe: glyceraldehydephosphate dehydrogenase, glycerol-1-phosphate dehydrogenase, malate dehydrogenase, and glucose-6-phosphate dehydrogenase, malic enzyme; and glycerol-1-phosphate oxidase. An increase of activity, proceeding periportally-pericentrally, was shown by glutamate dehydrogenase and TPN-specific isocitrate dehydrogenase. Like cytochrome oxidase, lactate dehydrogenase and succinate dehydrogenase showed slightly greater activity in the periportal region. None of the dehydrogenases which were studied appeared to occur within the nucleus. A positive correlation between quantitative and histochemical determinations was shown for a considerable number of extra- and intramitochondrial enzymes, supporting the tentative conclusion that a significant difference exists between periportal and pericentral parenchymal cells as concerns metabolic activity: oxidative processes taking place primarily in the periphery, biosynthetic processes in the central area. If so, a complementary relationship would appear to exist between glutamate dehydrogenase and TPN-specific isocitrate dehydrogenase in view of their intralobular distribution pattern. Also discussed, in the light of intralobular distribution patterns, are 2 different pathways for extramitochondrial citrate metabolism.

- 7273 FLUID RETENTION IN THE LIVER AFTER GASTROINTESTINAL RESORPTION OF WATER. (Ger.) Haberich, F. J. (Free U. Berlin), O. Aziz and P. E. Nowacki. Pflueger. Arch. Ges. Physiol. 288(4):306-314, 1966.

Within 5 min. after intragastric admin. of water warmed to body temperature (3 ml/100 g), approx. 15% of the total amount admin. had passed into the liver, which eventually stored as much as 20% of the total. (The increase of wet wt. equaled the increase of water content exactly, thus excluding any increase of blood content.) During the first 20-30 min. after admin. of the water, osmotic pressure in the portal blood flow decreased markedly (30-40 milliosmols at the end of 5 min.), while that of arterial blood remained unchanged. The authors conclude that this mechanism enabled the liver to function as a dam during the period of hypotonicity of the portal blood flow, storing the resorbed water and thus preventing or delaying its passage into the general circulatory system.

- 7274 DEPENDENCY OF HEPATIC BLOOD FLOW UPON PRESSURE. (Ger.) Messmer, K. (U. Munich, Germany), W. Brendel, K. Devens and H. J. Reulen, Pflueger. Arch. Ges. Physiol. 289(1):75-90, 1966.

In dogs with previously established ligature of the gastroduodenal artery (to permit accurate measurement of blood flow through the hepatic artery into the liver), systemic hypotension was induced by bleeding, ganglionic blockade via i.v. infusion of trimetaphan, or the i.v. admin. of coli endotoxin. In the first two cases,

HEPATIC METABOLISM

determinations of total blood flow through the liver, hepatic arterial and portal venous flow, indicated that reduction of the vol. of flow in passive response to hypotension tended to be countered by different autoregulatory mechanisms affecting the hepatic artery and the portal vein, resp. In the hepatic artery, a compensatory dilatation, probably of myogenic origin, appeared to be primarily involved. In the case of the portal vein, a compensatory response on the part of the mesenteric circulatory system appeared to be indicated, although the mechanisms through which this might be mediated could not be defined. The absence of similar response when systemic hypotension followed admin. of endotoxin was ascribed, at least in part, to the latter's effects on smooth muscle.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

- 7324 IN VITRO DETERMINATION OF DEFOAMING INACTIVATION OF SILICONE ANTACID TABLETS. (E.) Rezak, M. (Reed & Carnrick Pharm., Kenilworth, N. J.). J. Pharm. Sci. 55(5):538-539, 1966.

An in vitro procedure is described for evaluating the defoaming activity of the activated silicone defoamers (e.g., simethicone) which are frequently added to antacids (especially, when given in tablet form) for the purpose of dispersing gas in vivo. Among the defoamer-antacid combinations tested, there appeared to be a very wide range of effectiveness, in terms of such defoaming action, depending in part on the antacid's tendency to inactivate the defoamer. A considerable loss of defoaming activity was also seen, in some cases, following storage of the tablets.

- 7325 DIRECT VISION OF THE AMPULLA OF VATER THROUGH THE GASTRODUODENAL FIBER-SCOPE. (E.) Watson, W. C. (U. Glasgow, Scotland). Lancet 1(7443):902-903, 1966.

A method is described for examination of the ampulla of Vater using the gastroduodenal fibroscope. Consecutive photographs revealed the pancreatic duct orifice in the center of the pouting ampulla during a period of spontaneous constriction and closure. The sphincter of Oddi was seen fully open at the moment of i.v. inj. of secretin; 60 seconds later, the first bubbles of pancreatic juice were beginning to appear and a flow of juice was observed immediately after. The ampullary zone was seen in 5 patients. Feasibility of this method in the diagnosis of obstructive jaundice is being assessed.

- 7326 IMPROVEMENT OF THE QUALITY OF BARIUM SULFATE SUSPENSIONS FOR GASTRO-INTESTINAL PASSAGE BY THE ADDITION OF POLYSACCHARIDE SOLUTIONS. (Ger.) Läser, S. (S. Laser Inst. Radiol., Basel, Switzerland). Schweiz. Med. Wschr. 96(19):633-638, 1966.

Addition of a stabilized pectin-sorbitol soln. resulted in stimulation of gastric peristalsis, accelerated gastric emptying without the need of other drugs (e.g., morphine or insulin), more rapid demonstration of the duodenal bulb and passage, and demonstration of larger areas of the digestive tract at the same time. Passage time was also briefer; survey pictures were taken at standard intervals (15-30 min., 2 hr., and 6 hr.). The constipating effect of the barium suspension in aged patients was also eliminated by addition of pectin-sorbitol soln. The optimum dose of sorbitol was 10-15 g; larger doses further accelerated passage of the contrast medium, but the tract was not visualized as well, especially the small intestine. Alginate, carrageen, and tragacanth had similar effects on the stomach and upper small intestine; carboxymethylcellulose, propylene glycol alginate, and carubin were inactive, and gum arabic had a dubious effect. The presence of acid groups was necessary for activity upon gastric and small intestinal peristalsis.

- 7327 THE DETECTION OF OCCULT BLOOD IN FAECES. (E.) Paver, W. K. A. and P. Goldman. Med. J. Aust. 1(16):669-670, 1966.

Nine hospital patients with no apparent gastrointestinal lesions were maintained for 13 days on a diet completely free from meat and green vegetables; 12 ml of blood per day (in orange juice) were admin. on days 5, 6, 7, and 8. All fecal specimens passed by these patients were subjected to 7 different chemical tests, including 'Hemotest', 'Occultest', orthotolidine 33%, orthotolidine 5%, benzidine (10 and 8 drops), and Hughes modified benzidine. A total of 42 tests were performed on each fecal specimen. Variation of results was seen with the 'Hemotest' and orthotolidine 5% test; no false positive results occurred after the third day of dieting; admin. blood was not detected in every case until 48 ml of blood had been admin. over 4 days. The 'Occultest' and orthotolidine 33% test were too sensitive and showed 26% and 28%, resp., false positive reactions even after 4 days of dieting. Results with the benzidine tests were similar to those obtained with the 'Hemotest' and orthotolidine 5%, although they were a little more reliable in the detection of blood. In general, the benzidine tests appeared a little more effective than the orthotolidine tests, although, since benzidine is not readily available, the orthotolidine 5% test is only a little inferior.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

- 328 APPARATUS FOR EASY AND CONTROLLABLE GAS INSUFFLATION OF THE PERITONEUM FOR LAPAROSCOPY. (Ger.) Eisenburg, J. (U. Munich, Germany). Klin. Wschr. 44(10):593-594, 1966.
- An automatic apparatus for delivery of oxygen or (preferably) carbon dioxide under controlled pressure and flow rate (1000 ml/min. at no more than 10 mm Hg at the needle's orifice) is described. Three pressure gauges are included, as well as a glass tube containing a light ball that floats upon the gas current; if this ball cannot be seen, the needle is improperly placed or lies against one of the abdominal organs. An unspecified large number of patients underwent laparoscopy using this apparatus. There were no complications, even in patients with peritoneal inflammation or adhesions. Gas pressure and flow are controlled automatically; for example, the apparatus shuts off if the insufflation pressure rises above about 50 mm Hg.
- 329 PREPARATION OF PATIENT FOR PROCTOSIGMOIDOSCOPIC EXAMINATION PERFORMED IN THE OFFICE. (E.) Riley, C. R. Dis. Colon Rectum 9(3):207-209, 1966.
- Two blind studies (on 50 subjects each time) were conducted on the effects of a sodium phosphate enema (120 ml), a microenema (6 ml), and a suppository. Satisfactory visualization of the rectum was possible in 90% after admin. of the phosphate enema, in 60% given the microenema, and in 30% given the suppository; in another study, visualization of the rectum was possible in 78% after admin. of the phosphate enema.
- 330 VASOPRESSIN AS AN ADJUNCT TO SPLENOPORTOGRAPHY. (E.) Edlich, R. F. (U. Minnesota Sch. Med., Minneapolis), R. M. Ferlic and E. F. Bernstein. Arch. Surg. (Chicago) 92(5):802-804, 1966.
- Splenic artery blood flow and portal venous pressure (measured by a small branch of the superior mesenteric vein) were reduced by 56% and 50%, resp., in 10 adult mongrel dogs following vasopressin infusion (0.01-0.02 pressor U/kg/min. for 15 min. via the femoral vein). These values were also reduced 47% following vasopressin infusion in 10 dogs with portal hypertension secondary to portal vein ligation. Ligation itself reduced the splenic artery flow 38% and increased the portal venous pressure about 25%. Vasopressin infusion in the controls caused a 15 mm Hg increase in systolic pressure and a decrease of 10 mm Hg in diastolic pressure in the aorta; aortic pressure in the test dogs was not affected except by the ligation itself, which produced a systolic and diastolic reduction of 25 and 15 mm Hg, resp. Admin. of vasopressin to the test dogs reduced postsplenic puncture bleeding from 30.4 ± 6.4 to 11.6 ± 2.1 g. (av. bleeding in controls was 5.5 ± 1 g). In the test animals, vasopressin also enhanced radiographic visualization of cinesplenoportograms (using 10 ml of 50% sodium diatrizoate) and reduced the splenic pulp destruction at the nj. site by 50%.
- 331 INHIBITION OF ACETYLCHOLINESTERASE BY SOME ORGANIC CONTRAST MEDIA. A PRELIMINARY COMMUNICATION. (E.) Lasser, E. C. (U. Pittsburgh Sch. Med., Pa.) and J. H. Lang. Invest. Radiol. 1(3):237-247, 1966.
- 332 RADIOTELEMETRY AND THE GASTROINTESTINAL TRACT. (E.) Kay, A. W. (U. Glasgow, Scotland). J. Indian Med. Prof. 13(1):5678-5679 & 5681, 1966.

GASTROINTESTINAL DISEASES

GENERAL

- 351 EFFECT OF STREPTOMYCIN ON IMMUNOGENESIS IN TYPHOID. (Rus.) Gukasian, G. B. (Inst. Epidemiol. & Hyg., Min. Health Armenian SSR, Erevan). Zhur. Mikrobiol. 43(4):59-64, 1966.
- In mice and rabbits which had undergone a complete course of immunization with anti-typhoid vaccine, the admin. of av. therapeutic doses of streptomycin 2-2 1/2 mo. later, for 10 days, produced an effect equivalent to that of revaccination. The antibiotic stimulated plasma cell formation, raised agglutinin titers, enhanced phagocytosis, and increased resistance to reinfection.
- 352 COMPARATIVE VIRULENCE OF Entamoeba histolytica STRAINS ISOLATED FROM PATIENTS AND DIFFERENT GROUPS OF CARRIERS. (Rus.) Mizgireva, M. F. (Ashkhabad Inst. Epidemiol., USSR). Med. Parazit. (Moskva) 35(2):201-204, 1966.
- Comparative examination of cultures of Entamoeba histolytica isolated from patients with amoebiasis (Group 1) and from carriers of different groups (convalescent from amoebiasis (Group 2), having contacts with patients (Group 3), asymptomatic carriers whose contact with patients was not established (Group 4)) was carried out. The study was made in Ashkhabad from 1959-62. A total of 78 strains were tested in 1791 white immature rats. The 48 hr. culture was intracecally induced after laparotomy and the rats were sacrificed after 7 days. The av. virulence of the strains in groups seemed to be arranged in a descending order. Most virulent were the cultures isolated from Group 1, then from Group 2, from Group 3, and the least virulent were those recovered from Group 4. The percentage of rats with lesions was, in Group 1 (total 679 rats) 34.8%; in Group 2 (total 226 rats), 26%; in Group 3 (total 715 rats), 16.7%, in Group 4 (total 171 rats), 14.6%. The av. severity of lesion gradually increased being highest in Group 1, and lowest in Group 2. Lower virulence of E. histolytica strains recovered from Group 2 and from Group 3 and approximation of their virulence to that of strains usually isolated from asymptomatic carriers indicates a possibility of changes in virulent properties depending upon conditions of existence and biologic forms of the parasite. This favors the existence of a single species of E. histolytica producing both disease and carrier state.
- 353 EXPERIENCES WITH ADULT Entamoeba histolytica INFECTIONS WITH THE CLINICAL FEATURES OF DYSENTERY. (Hun.) Münnich, D. (Hajdú-Bihar County Council Hosp., Debrecen, Hungary) and J. Szöör. Orv. Hetil. 107(8):353-358, 1966.
- Over the period from January 1, 1961 to March 1, 1965, 1514 patients with the clinical picture of dysentery were treated. In only 567 cases (37%) was Shigella infection verified bacteriologically. In 307 cases, Entamoeba histolytica was found in the stools, and infection with this pathogen was confirmed in 114 cases (37%). Concomitant infection with intestinal bacterial pathogens was observed in 21.6% of these cases (Shigella in 14.0%, Salmonella in 6.0%), and concomitant intestinal protozoal or helminthic infections were present in 10.5% and 7.0%, resp. Such infections may facilitate tissue invasion by E. histolytica, with the resultant development of chronic dysentery or chronic enteritis. For the treatment of mild cases of amebiasis, and in some moderately severe cases, the domestic product, "Fumagillin" proved effective, but it is not suitable for the treatment of severe cases (e.g., the extra-intestinal form). In these, the combination of "Enteroseptol" + "Delagil" was most effective. With the various drugs administered, alone or associated, clinical improvement was achieved in 31%, elimination of all symptoms in 63%. Parasitologic findings improved in 15% and became negative in 75%. The best guarantee against reinfection is active anti-amebic treatment of the environment.
- 354 THE POSSIBILITY OF DISSEMINATION OF S. enteritidis INFECTION THROUGH THE RESPIRATORY ROUTE. (Pol.) Szmunn, W. (Provincial Sanit.-Epidemiol. Station, Lublin, Poland), J. Sikorska, E. Szymanek, A. Mikosz and L. Cechowicz. Przegl. Epidem. 19(4):433-439, 1965.
- From July 1964 to February 1965, 309 cases of Salmonella enteritidis infection were registered in Lublin Province, almost half of them in children under 6 mo. old,

GENERAL

of which 9.6% were neonates (2-9 days old). The disease was especially acute in the neonates, among whom the mortality was 25%. In older children and adults, the course was generally mild or even asymptomatic. S. enteritidis was isolated from the stool or urine in 98% and 68% of the cases studied, resp., and sometimes from both, and from the blood, in 17%. In addition, presumably as a result of secondary infection it was isolated from the upper respiratory tract in 37 of the 131 children from whom throat and nasal swabs were obtained for bacteriologic study. In 2 cases, the pathogen was found in both the throat and nose. Among the 64 cases re-examined 3 or more times, 25 (39%) were identified as carriers. The organisms could be demonstrated in the upper respiratory tract for as much as 144 days after the infection. In 10 children, the carrier state persisted for 60-80 days; usually, it was permanent. S. enteritidis was twice isolated from the air of the wards where children with the pathogen in their throats were hospitalized, and measures should be taken to guard against such air-borne infection. All the strains of S. enteritidis isolated were resistant to antibiotics.

- 7355 FUNCTIONAL CONDITION OF THE STOMACH AND EXTERNAL SECRETORY ACTIVITY OF THE PANCREAS IN WORKERS EXPOSED TO THE EFFECTS OF NITROBENZENE DERIVATIVES. (Rus.) Kleiner, A. I., E. V. Krylova and A. M. Levendiuk. Gig. Trud. Prof. Zabol. 9(9):40-47, 1965.

A complex study of the secretory, motor and excretory function of the stomach and of the external secretory activity of the pancreas in 70 workers, all of whom were exposed to the action of nitrobenzene derivatives for 3 to over 10 yr., revealed in most cases pathological changes, mainly functional. There was a tendency towards inhibition of the gastric secretion and motoricity, especially noticeable in the phase of the composite-reflex secretion, along with a definite correlation of these changes with the extent of exposure and degree of manifestation of clinical symptoms of chronic poisoning. The external secretion of the pancreas was characterized by dyspancreatization of the pancreatic juice enzymes (especially in relation to trypsin and lipase) and frequent deviation of diastase following double-glucose loading. Pathological shifts in the gastric and pancreatic functions occurring in a large number of the workers examined make it necessary to consider the state of digestive organs while conducting preliminary and periodic medical examinations in corresponding industries and also during treatment of chronic occupational poisoning.

- 7356 STUDIES ON ORNITHINE CARBAMYL TRANSFERASE AND ISOCITRIC DEHYDROGENASE IN TYPHOID FEVER. (It.) Tigano, F. (U. Messina, Italy), F. La Rosa and V. Romeo. Gior. Mal. Infett. 17(12):898-901, 1965.

Determination of serum ornithine carbamyl transferase and isocitric dehydrogenase levels was performed in 26 patients (11-55 yr. old) with bacteriologically and serologically proven typhoid fever. Duration of disease was 1 wk. in 7 patients, 2 wk. in 10, 3 wk. in 2, and 4 or more wk. in 7; 7 had been treated regularly and irregularly with chloramphenicol, 6 with a combination of antibiotics, and 11 had not been treated. Increased serum levels of both enzymes were found in 20 patients. Pathological levels were observed in all duration periods. Highest levels were seen in forms with the most severe degree of toxemia, regardless of duration of the disease. Normalization occurred parallel to clinical improvement. The most effective treatment seemed to be a combination of prednisone and chloramphenicol. It is suggested that the increased levels of ornithine carbamyl transferase and isocitric dehydrogenase observed in patients with typhoid fever are due to hepatic parenchymal damage.

- 7357 MORPHOLOGICAL STUDIES IN RATS, WITH PARTICULAR REFERENCE TO THE DIGESTIVE TRACT FOLLOWING ACUTE TREATMENT WITH SEROTONIN. (It.) Montagnani, M. (U. Siena, Italy), P. F. Bayeli and G. Bassi. Boll. Soc. Ital. Biol. Sp. 42(5):241-245, 1966.

The effect of acute admin. of serotonin on various organs was studied in 12 white rats following i.p. inj. of 5 mg/100 g in a single dose or repeated after 3, 12, or 24 hr. Congestion, regression, inflammation, necrosis, and other changes were frequently observed in the liver, spleen, kidney, lung, stomach, and large and small

GENERAL

intestine, but were rarely seen in the heart. The most frequent stomach lesions were erosions of the glandular mucosa (91.6%), stasis (41.6%), and inflammatory lesions; in only 1 case was the stomach normal. Among the hypotheses advanced to explain the appearance of these lesions are tissue anoxia due to the vasoconstricting effect of serotonin or a hyperemic effect due to the liberation of histamine. Contrary to other published reports, the authors failed to observe necrosis of the renal cortex or significant alterations of the heart values. (See also 7358.)

- 7358 MORPHOLOGICAL STUDIES IN RATS, WITH PARTICULAR REFERENCE TO THE DIGESTIVE TRACT AFTER CHRONIC TREATMENT WITH SEROTONIN. (It.) Bayeli, P. F. (U. Siena, Italy), G. Bassi and M. Montagnani. Boll. Soc. Ital. Biol. Sper. 42(5):245-248, 1966.

The effect of chronic admin. of serotonin on various organs was investigated in 16 white rats after i.p. inj. of 6 mg/day in 7 rats for 4-24 days (Group 1; total 24-144 mg); 7 mg/day in 5 rats for 1-41 days (Group 2; total 7-287 mg); 9 mg/day in 3 rats for 1-4 days (Group 3; total 9-36 mg); 10.5 mg/day in 1 rat for 55 days (Group 4; 577.5 mg). Various stages of congestion, regression, ischemia and necrosis in relation to the amount of serotonin admin. were observed in all organs (liver, small and large intestine, stomach, lung, and kidney) except the heart. Lesions were most frequent in the glandular portion of the stomach, with progressive increase in severity in proportion to the amount of serotonin admin. Stomach lesions ranged from gastritis, necrosis, and degeneration of the superficial layers of the mucosa after smaller doses to erosion and ulcerations of the mucosa after larger doses. Experimental intoxication of rats with serotonin differs from carcinoid syndrome inasmuch as the heart is not affected. The importance of serotonin in the pathogenesis of peptic ulcer formation in man is discussed. (See also 7357.)

- 7359 AMOEBIASIS--A DIAGNOSTIC PROBLEM IN GREAT BRITAIN. (E.) Wright, R. (Radcliffe Infirmary, Oxford, England). Brit. Med. J. 1(5493):957-959, 1966.

Two cases of amebic colitis and 6 cases of hepatic or pleuropulmonary amebiasis are described in detail. All of the patients were male, 33-67 yr. One patient in each group died and surgical procedures were carried out in 4 cases before a diagnosis had been made. Two patients had never been in endemic areas. None of the patients with hepatic or pleuropulmonary amebiasis gave a history of dysentery but had the common clinical features of pain over the liver, often referred to the right shoulder, fever, malaise and loss of weight. The possible use of serological tests in the diagnosis of amebiasis was discussed.

- 7360 A, B, AND O SUBSTANCES IN GASTROINTESTINAL CARCINOMA. (E.) Davidson, I. (Mt. Sinai Hosp. Med. Ctr., Chicago, Ill.), S. Kovarik and Chang Ling Lee. Arch. Path. (Chicago) 81(5):381-390, 1966.

The presence of water-soluble blood group antigens A, B, AB, and O was investigated in formalin-fixed, paraffin-embedded tissues of the gastrointestinal tract (including stomach, small intestine, ascending and transverse colon, and proximal portion of the descending colon) in 81 adenomatous polyps and adenocarcinomas, and in controls. Immune rabbit anti-A, human anti-A and anti-B sera, and extracts of Ulex europaeus, conjugated with fluorescein isothiocyanate, were used for detection of the antigens. Blood group substances were found in normal cells, adenomas, and in cancer cells that have preserved the ability to produce mucus. Blood group substances could not be detected in all anaplastic cells that ceased to secrete mucus, nor in some that continued to secrete. The failure to secrete the blood group antigen is interpreted as a manifestation of dedifferentiation of the cancerous process.

- 7361 PATHOLOGICAL STUDIES ON THE INDUCED CANCERS OF THE GASTRO-INTESTINAL TRACTS IN THE BUFFALO RATS FED N,N'-2,7-FLUORENYLENEBISACETAMIDE. (E.) Nagayo, T. (Nagoya City U. Sch. Med., Japan) and M. Ito. Nagoya Med. J. 11(1):19-30, 1965.

Beginning at age 1.5-2 mo., 6 groups of male Buffalo rats were fed N,N'-2,7-fluorenylenebisacetamide (0.025% in diet; continued until death). Other treatment,

GENERAL

given in an attempt to increase the incidence of gastrointestinal tumors, was: orchiectomy alone (Group I) or together with diethylstilbestrol (Group II) immediately before carcinogen treatment; or orchiectomy with induction of traumatic stomach ulcers after 1 and 7 mo. (Group III), 3 mo. (Group IV), or 5 mo. (Group V). Group VI received I without other treatment. Group VII (orchiectomized), VIII (induction of ulcers at 3 or 4 mo.), and IX (untreated) did not receive the carcinogen; there were no tumors in these groups. In the 74 evaluable animals admin. the carcinogen, the av. survival times were about the same in all groups (7.3-7.8 mo. after the beginning of carcinogen admin.) except for Group II (6.4 mo.). Digestive tract cancers developed in 43 of the 74 rats; there was 1 stomach cancer in Group III, 3 duodenal tumors in Groups I, IV, and V, and 43 intestinal cancers in the entire group, which included all animals with stomach or duodenal tumors. There were also 16 benign tumors or focal hyperplasia of the stomach. Tumor frequency was significantly less, and av. tumor size was smaller, in Group II, except that there were 10 mammary tumors in this group (the only other mammary tumor appeared in 1 rat of Group VI). The incidence of tumors of other sites (lung, pancreas, salivary gland, etc.) was about the same in all treated groups. Most rats (43) had multiple small intestinal tumors over 80% of which developed in the jejunum; a few very small colon tumors also developed. All gastric and duodenal tumors were well-differentiated adenocarcinomas, as were most of the nodular intestinal tumors; some of the latter, however, were of a lower degree of malignancy, while 2 were highly anaplastic and were later successfully carried through 4 or more transplant generations in weanling Buffalo rats of both sexes.

7362

MALIGNANT TUMORS OF SALIVARY GLAND ORIGIN: 37-YEAR REVIEW OF 184 CASES.

(E.) Rosenfeld, L. (Vanderbilt U. Sch. Med., Nashville, Tenn.), D. G.

Sessions, B. McSwain and H. Graves, Jr. Ann. Surg. 163(5):726-735, 1966.

Data on 99 male and 85 female patients with salivary gland tumors (excluding metastatic carcinomas or lymphomas) seen between 1928-1965 are reviewed. Of the tumors, 60% (112) originated in the parotid gland, 24 in the submaxillary gland, 4 in the sublingual gland, and 23 in the palate or maxilla. There were 5 children under 10 in this group; tumor types were adenocarcinoma (1), low-grade mucoepidermoid carcinoma (2) or unclassified carcinoma (2). There were only 2 squamous cell carcinomas in patients under 41, and about 50% of the 20 mucoepidermoid carcinomas were seen in patients under 51; the age incidence was otherwise rather evenly distributed as to cell type. Most patients (127) were between 40-80 yr. old at onset. Many of the tumors had an indolent clinical course; the duration of symptoms before definitive treatment was under 1 yr. in 42%, up to 5 yr. in 31%, 5-15 yr. in 17%, and 16-over 30 yr. in 9%. Of the 81 patients who died of malignant disease, 35 had cancer of over 5 yr. duration (the duration was over 15 yr. in 12 cases). Extended survival was possible even in the presence of lung metastases, recurrent local disease, or lymph node extension. The survival rates at 5, 10, and 15 yr. were 70 of 132 (55%; 4 with disease), 31 of 79 (42%; 2 with disease), and 8 of 49 (18%; 1 with disease), resp. Wide surgical excision, its extent depending on tumor type, was the most effective treatment. The natural course of most of these tumors was characterized by long duration, repeated local recurrences, and frequent metastatic spread to the local lymph nodes and lungs. The tumors were classified into 8 cell types, of which 4 (adenocarcinoma, high-grade mucoepidermoid carcinoma, unclassified carcinoma, and squamous cell carcinoma) were aggressive and had a poor prognosis, and the other 4 (acinic cell, low-grade mucoepidermoid, or adenoid cystic adenocarcinomas, and malignant mixed tumors) were less aggressive but difficult to eradicate.

7363

SCHISTOSOMIASIS: EXPERIMENTAL SURGICAL REMOVAL OF ADULT WORMS. (E.)

Goldsmith, E. I. (New York Hosp., N. Y.) and B. H. Kean. Gastroenterology

50(6):805-807, 1966.

Two baboons infected with 5000 or 34,000 cercariae of *Schistosoma mansoni* developed active disease 6 wk. later; the former animal was clinically well, but the latter developed melena, diarrhea, and debilitation. The apparatus used to remove the adult worms consisted of an extracorporeal mechanical pump with a filter, originally

GENERAL

designed for blood transfusions, which was connected with the isolated portal vein and the right common iliac vein. When the pump was in position, attempts were made to drive the adult worms from the blood vessels of the intestine into the portal circulation by admin. of Fuadin, Nembutal, and tartar emetic. Treatment with tartar emetic resulted in the expulsion of most of the adult worms in each host. Autopsy studies demonstrated only 4 worms in the colon serosa vessels in the animal with the lighter infestation, and 40 adult worms in the other; an estimated 97.5% of the adult worms had been removed from the latter animal. No adult worms were found in the hepatic vessels of either animal.

364 FLOCCULENCE EFFECT IN SIALOGRAPHY. (E.) Kettunen, K. (Maria Hosp., Helsinki, Finland). Ann. Chir. Gynaec. Fenn. 55(2):152-153, 1966.
Diagnostic pitfalls during sialography with aqueous or oily contrast media are described and illustrated. Avoidance of too rapid inj. and overpressure, identification of contrast medium in the mouth and pharynx, and the tendency of iodized oils to form droplets in the saliva (thereby creating a flocculence effect) are discussed with particular reference to diseases in which the salivary ducts are impaired.

365 SURVIVAL IN PATIENTS WITH THE ZOLLINGER-ELLISON SYNDROME TREATED BY TOTAL GASTRECTOMY. (E.) Wilson, S. D. (Marquette U. Sch. Med., Milwaukee, Wis.) and E. H. Ellison. Am. J. Surg. 111(6):787-791, 1966.
Analysis of 248 patients with the Zollinger-Ellison syndrome revealed highest survival rates (13 of 15 patients; 87%) when the initial gastric resection was total gastrectomy; survival was 73% (46 of 63) after treatment by subtotal then total resection; 53% (79 of 164) after subtotal resection; 27% (29 of 106) in patients not subjected to resection. Among 78 patients known to have undergone total gastrectomy, 59 patients survived (25 for at least 2 yr., 15 for at least 3 yr., and 2 over 10 yr.); overall mortality (6 mo. to 11 yr. follow-up) was 24% (19 patients); post-operative mortality was 15% (12 patients). Five patients died from shock or continued bleeding 36 hr. after surgery. Four patients died 2-11 days after surgery, 3 from sequelae of anastomotic leaks and 1 from pneumonia. Three patients died 2-4 wk. after surgery, 1 suddenly with pulmonary embolus and 2 with anastomotic leaks resulting in abscess formation and fistula. Seven of the 12 early deaths occurred in patients requiring emergency surgery for massive gastrointestinal hemorrhage or perforation who had an av. of 4 surgical procedures. There have been only 4 deaths that can be attributed to tumor and cachexia, and these occurred in patients 10 mo., 1 yr., 2 yr., and 6 yr. after total gastrectomy. Early tissue diagnosis and elective total gastrectomy combined with tumor excision when feasible are the procedures of choice in the treatment of ulcerogenic tumors of the pancreas.

366 THE UNOPERATED ABDOMINAL AORTIC ANEURYSM. (E.) Klippel, A. P. (Washington U. Sch. Med., St. Louis, Mo.) and H. R. Butcher, Jr. Am. J. Surg. 111(5):629-631, 1966.
Thirty patients (22 men and 8 women; median age 69 yr.) with abdominal aortic aneurysms not subjected to surgery (either because not advised or refused) were followed for 5 yr. or until they died. Of 9 (30%) survivors, 8 were alive 5 yr. after diagnosis and 1 was alive 4 yr. after diagnosis; 4 had aneurysms that measured 5 cm or less. Death occurred in 21 of 30 (70%) patients not treated surgically, the causes of which were arteriosclerotic myocardial disease (11), cerebrovascular disease (4), rupture of aneurysm (2), uremia (1), auto accident (1), carcinoma of the lung (1), and perforated duodenal ulcer (1). In the 2 patients who died from rupture of the aneurysm, this complication occurred 27 and 23 mo., resp., from the date of diagnosis. It is concluded that only those patients who have no serious concurrent vascular disease and whose aneurysm is 6 cm or more in diameter should have aortic replacement.

367 EFFECTS OF DIGESTIVE TRACT RESECTION IN DOGS. (ANOTHER VITAL ROLE OF THE GASTROINTESTINAL TRACT OUTSIDE OF DIGESTION.) (Fr.) Dogru, M. (U. Ankara, Turkey) and R. Tanalp. Rev. Med. Moyen Orient 23(1):83-87, 1966.
The effects of digestive tract resection were studied in 12 dogs subjected to

GENERAL

excision of a portion of the digestive tract extending from the cardia to the rectum, the spleen and the pancreas. The liver and hepatic artery were left intact. The average survival was 3 hr.; 1 dog survived for 4.5 hr. Arterial blood pressure decreased markedly immediately after surgery, increased after 1 hr. to less than basal values, and remained stabilized until shortly before death. Hematologic tests revealed increased ammonia levels and acidosis; despite treatment with i.v. bicarbonate solution, animals survived a maximum of 5 hr. Histological examination revealed marked congestion of the liver, kidneys, and lungs. In an effort to determine whether or not serotonin was responsible for the increased capillary permeability and fall in blood pressure, serotonin levels were assayed but no changes were observed. Results suggest an endocrine activity of the gastrointestinal tract.

- 7368 EARLY REOPERATION IN ABDOMINAL SURGERY. STATISTICS ON 2,571 REOPERATIONS (Fr.) Lagache, G. (City Hosp., Lille, France), B. Combemale and C. Proye. Lille Chir. 21(1):20-26, 1966.

Of 2,571 patients subjected to abdominal surgery from 1960-65, 39 required reoperation, among whom 13 died (reoperative mortality = 33%). With regard to initial surgery, frequency of reoperation and mortality were 4 of 67 and 50%, resp., following surgery of the small intestine; 11 of 411 and 45%, resp., stomach; 8 of 262 and 37%, resp., colon and rectum; 3 of 653 and 33%, resp., appendix. The cause of reoperation among 32 justifiable reoperations was internal hemorrhage (7), hematoma (2), intestinal obstruction (17), and peritonitis (6). Death due to unjustifiable reoperation occurred in 7 of 39 reoperations, while 12 deaths were attributed to failure to reoperate. The authors feel that the best means of preventing early reoperation is by perfecting surgical technics.

- 7369 EARLY REOPERATION IN ABDOMINAL SURGERY. (Fr.) Razemon, P. (U. Lille Sch. Med. Pharm., France), M. Ribet, C. Gautier-Benoit, H. P. Leclerc and A. Hassoun. Lille Chir. 21(1):3-19, 1966.

Of 2,055 patients subjected to abdominal surgery from 1959-63, 91 (4.4%) required reoperation. With respect to initial surgery, reoperation was most frequent following emergency surgery for abdominal injury and contusions (12.2%; mortality 14%), colon and rectum surgery (9.2%; mortality 62%), portacaval shunt (9%; mortality 0%), and esophageal surgery (7.1%; mortality 80%). High mortality rates were also seen after reoperations of the stomach and duodenum (64%), uterus (50%), and pancreas and biliary tract (35%). The cause of reoperation and number of cures were as follows: intestinal obstruction (9 of 10), acute peritonitis (8 of 23), subacute peritoneal syndrome (10 of 15), evisceration (5 of 16), hemorrhage (7 of 11), diagnostic error (3 of 5), and errors in technic (14 of 25). Of 43 deaths following reoperation, 6 were due to progression of the initial disease, 23 to inefficacy of reoperation, and 14 to complications not related to the initial disease; 7 deaths occurred in patients not subjected to reoperation. Among 8 patients reoperated twice, 4 were cured, 2 died, and 2 required another operation. Errors in indication for surgery occurred in only 12 (0.58%) patients.

- 7370 ABDOMINAL MANIFESTATIONS OF SITUS INVERSUS IN INFANTS AND CHILDREN. (E.) Fonkalsrud, E. W. (U. California Sch. Med., Los Angeles), R. Tompkins and H. W. Clatworthy, Jr. Arch. Surg. (Chicago) 92(5):791-795, 1966.

From 1950-64, 37 patients (22 male and 15 female; 46% under 1 mo. old at time of diagnosis) were treated for situs inversus at the Columbus Children's Hospital. Among these were 15 patients with major intraabdominal anomalies and 15 with cardiac anomalies. Intraabdominal lesions were rarely observed (2 of 37 cases) in patients with isolated dextrocardia. Intraabdominal anomalies included congenital obstruction of the gastrointestinal tract in 33% (8 of which were atresias or stenoses of the duodenum or jejunum), incomplete fixation of the bowel mesentery in 7 patients. More than 85% of the lesions were surgically correctable, yet 9 of the patients in this group died. Four deaths occurred among 6 patients with associated major cardiac anomalies. The importance of preoperative diagnosis is stressed in view of the fact that in 2 patients operative procedure and later care were confusing when the surgical incision was placed on the incorrect side of the abdomen because visceral transposition was not recognized.

GENERAL

371 PERSISTENT ULCER AND ZOLLINGER-ELLISON SYNDROME. (Dut.) Hellemans, N. (U. Groningen, The Netherlands), W. G. R. M. De Boer and J. Julius. Nederl. T. Geneesk. 110(6):298-304, 1966.

In a 55-year-old man presenting with a duodenal ulcer and severe gastric hypersecretion, repeated surgical interventions over a period of approx. 3 yr. (including resection of the duodenal ulcer, which had extended to the pancreas, vagotomy + repeated resections of a recurrent peptic (jejunal) ulcer, and an intercurrent cholecystectomy) were unable to control either the gastric hyperacidity or recurrence of ulcer. The immediate cause of death was acute pancreatic necrosis. The presence of Zollinger-Ellison's syndrome (a polyglandular endocrine adenomatosis involving the parathyroids, adrenals and pancreas) was confirmed at autopsy. In another patient, age 48 at the time of extensive colonic resection for carcinoma of the transverse colon, recurrent duodenal and peptic (jejunal) ulceration in the presence of severe gastric hypersecretion suggesting Zollinger-Ellison's syndrome was only moderately responsive to conservative therapy over a period of approx. 6 yr. However, the pancreas proved normal at the time of a second gastric resection, and a gastrin-producing remnant of the antrum remaining from the original operation proved to be the source of both gastric hyperacidity and the recurrent ulceration.

372 EXPERIMENTAL INDUCTION OF CHRONIC, NON-NECROSING AMEBIASIS WITH OBSERVATIONS CONCERNING ITS PATHOGENESIS. (Ger.) Candreviotis, N. (Evangelismos Hosp., Athens, Greece). Zbl. Allg. Path. 108(5):493-506, 1966.

Trophozoites of axenic Entamoeba histolytica were inj. intrahepatically into 1 group of guinea pigs, 4-96 hr. before sacrifice; intramurally into the cecum, in another group, 5-30 days before sacrifice; and i.p. into a group of rabbits which received 4 inj. (at 7, 7 and 14 days, resp.), terminated 1 wk. before sacrifice. All groups developed non-necrosing, non-suppurative, non-ulcerative inflammations at the site of inj., similar to those seen in chronic amebiasis in the human. Leukocytic infiltration was followed by development of macrophagic granulomas and the latter, in turn, by the appearance of granulomas characteristic of the stage of induration which accompanies recovery. In the affected areas, the destruction of the amebic invaders could be followed in detail.

373 GASTROINTESTINAL FINDINGS IN CYSTIC FIBROSIS. (E.) Grossman, H. (Columbia-Presby. Med. Ctr., New York, N. Y.), W. E. Berdon and D. H. Baker. Am. J. Roentgen. 97(1):227-238, 1966.

Cystic fibrosis is usually accompanied by gastrointestinal tract involvement with clinical manifestations which differ at ages ranging from in utero to adulthood. Congenital intestinal obstruction is found in approx. 10% of infants born with cystic fibrosis. The major causes of this obstruction are meconium ileus and secondary complications such as pseudocysts and atresia. Inspissated small bowel contents after the newborn period may act as a "leader" in intussusception, simulate acute appendicitis, or cause intestinal obstruction ("meconium ileus equivalent"). Marked distention of the abdomen may be noted without intestinal obstruction. Ascites or edema, due to hypoproteinemia, may be the presenting syndrome. This may be secondary to malabsorption in the infant or due to cirrhosis in the older child. The association of diarrhea and considerable gas in the intestinal tract poses diagnostic problems. The pathogenesis of a bizarre pattern in the small and large intestine, calcification of the pancreas, and duodenal ulcers are less clearly understood than the other gastrointestinal findings mentioned.

7374 CHOLERA IN CHILDREN. (E.) Lindenbaum, J. (Pakistan-Seato Cholera Res. Lab., East Pakistan), R. Akbar, R. S. Gordon, Jr., W. B. Greenough III, N. Hirschorn and M. R. Islam. Lancet 1(7446):1066-1068, 1966.

An analysis was presented of 769 cases of bacteriologically documented cases of cholera treated over an 18-mo. period with 327 (42.5%) in children 0-10 yr. old. The clinical findings on admission showed that with the exception of patients less than 2 yr. the severity of dehydration was similar in adults and children; dehydration was less severe in those under 2 yr. Coma (highest incidence in 2-10 yr.) and convulsions due to hypoglycemia were seen only in those less than 7 yr. and prolonged

GENERAL

drowsiness (unrelated to blood sugar levels) was more common in children under 10 years than in other age groups. The incidence of hypothermia or fever was not age related. Therapy consisting of measurement of stool volume with fluid and electrolyte replacement, oral tetracycline and continual medical attention was similar for both children and adults. The mortality rate was the same for children, 0.61% (2 of 327) as the total mortality rate of 0.65% (5 of 769).

- 7375 PLASMA FATTY ACIDS IN PANCREATIC CYSTIC FIBROSIS AND LIVER DISEASE. (E.) Caren, R. (U. California Sch. Med., Los Angeles) and L. Corbo. J. Clin. Endocr. 26(4):470-477, 1966.

The fatty acid percentage composition of plasma total esterified, phospholipid, cholesterol ester, triglyceride and unesterified fatty acid fractions was analyzed by gas-liquid chromatography, and the absolute levels of each fraction were determined in 3 groups of patients. Characteristic alteration of the percentage composition of the plasma fatty acids was observed in patients with pancreatic cystic fibrosis. Palmitic, palmitoleic and oleic acids were elevated with concomitant depression of linoleic and arachidonic acids. Since hepatomegaly was noted in several of these children, the same study was performed on a group with Laennec's cirrhosis and hepatitis of recent origin. The same changes of the individual plasma fatty acids were seen in all patients with Laennec's cirrhosis, and were of greater magnitude. The changes in the hepatitis group paralleled those of Laennec's cirrhosis but were of less degree as was true in pancreatic cystic fibrosis. It was concluded that the plasma fatty acid changes in pancreatic cystic fibrosis were due to accompanying liver disease. The cholesterol ester fraction appeared to be the most sensitive indicator of liver disease.

- 7376 IMMUNOSEDIMENTATION PATTERNS IN PATHOLOGICAL HUMAN SERA. (E.) Córdoba, F. (U. Mexico, Mexico City), C. González and P. Rivera. Clin. Chim. Acta 13(5):611-625, 1966.

Further improvements are presented of the previously described technic of immunos sedimentation (gel plate immunoprecipitation of antigens separated by centrifugation in sucrose gradients). Utilizing this technic, characteristic protein patterns were obtained from the sera of patients with myeloma, macroglobulinemia, viral hepatitis, rheumatoid arthritis and acute pancreatitis. Serum from a case of hepatitis with transient hypergammaglobulinemia shows more 7 S γ_2 -globulin than found in normal serum. There is a marked increase of macroglobulins in the γ and in the α_2 region. No protein accumulated in region V (haptoglobins and glucoproteins; always prominent in normal serum). Immunoelectrophoresis of the sample with both antisera (pooled human serum and human γ -globulin) disclosed only an increased γ -globulin precipitate. Immunos sedimentation of the serum from a patient with cirrhosis of the liver shows spots which are less prominent. The albumin conc. seems lower and the 7 S γ_2 -globulins are increased. α_2 -Globulin produced a discrete spot accompanied with slight streaking of the γ zone, around the 10-15 S values, which is usually not present in normal samples. The sera from an acute pancreatitis case and cases of amebic liver abscess showed only minimal changes from normal serum.

- 7377 TERMINAL HEMORRHAGIC NECROTIZING ENTEROPATHY (THNE). A RETROSPECTIVE CLINICOPATHOLOGIC STUDY WITH A REVIEW OF LITERATURE. (E.) Bhagwat, A. G. (Cleveland Clin. Found., Ohio) and W. A. Hawk. Am. J. Gastroent. 45(3): 163-188, 1966.

A review of autopsy protocols and a review of pertinent literature are presented. Terminal hemorrhagic necrotizing enteropathy appears to be a clinicopathologic entity characterized by: (1) Almost exclusive appearance in elderly persons with significant heart disease; (2) Insidious but extensive hemorrhagic necrosis of the intestines usually within the distribution range of the superior mesenteric artery and unassociated with mesenteric vascular occlusion or significant stenosis, mechanical interference with mesenteric vasculature or primary arterial disease; (3) Most frequent association clinically with an episode of persistent hypotension and varied acute abdominal symptoms; (4) Rather characteristic gross and microscopic appearance of the intestine; (5) Probable functional vascular etiologic basis influenced by

neurohumoral and immunologic mechanisms leading to self-perpetuating vicious circles;
 (6) Usual acute fatal termination. Several theories are presented which seek to explain the genesis of extensive hemorrhagic intestinal necrosis without vascular occlusion. Sixteen case histories are appended.

7378 GASTRIC SECRETION WITH ULCEROGENIC ISLET CELL TUMOR. IMPORTANCE OF BASAL ACID OUTPUT. (E.) Aoyagi, T. (Mayo Clin., Rochester, Minn.) and H. J. Summerskill. Arch. Intern. Med. (Chicago) 117(5):667-672, 1966.

The 134 subjects in the study satisfied certain criteria: availability of gastric secretory data; the presence of gastroduodenal ulcer disease or the demonstration of gastric secretagogue activity from extracts of islet cell tumor; and the presence of carcinoma, adenoma, or hyperplasia of the islets. The series comprised 77 males, 55 females; sex was not reported for 2. Ages ranged from 12-74 yr. Basal acid output in patients with ulcerogenic islet cell tumor was significantly higher than in normal persons or in patients with duodenal ulcer. Maximal acid output following an augmented dose of histamine was significantly above normal, but gastric secretory responses to this and other stimuli did not differ significantly from those in patients with duodenal ulcer, when the stomach was intact, or with marginal ulcer, following gastric surgery. Basic acid output usually reliably indicated the possible presence of ulcerogenic islet cell tumor; measurements of stimulated gastric secretion and the ratio of basal to stimulated acid output yielded little additional diagnostic information.

7379 IMMUNITY TO Trichinella spiralis. I. THE IMMUNITY PRODUCED BY MICE TO THE FIRST FOUR DAYS OF THE INTESTINAL PHASE OF THE INFECTION. (E.) Denham, D. A. (U. Cambridge, England). Parasitology 56(2):323-327, 1966.

Mice infected with Trichinella spiralis larvae (400 larvae/mouse) were treated with methyridine (3 inj. of 500 mg/kg over 18 hr., s.c.) beginning 7, 48, 72, or 96 hr. after infection; examination of treated mice showed complete or nearly complete destruction of the parasites. The immunity produced by these infections was then tested by further challenge with T. spiralis larvae 12-26 days after the initial infection. Single infections of 48 hr. duration and single or triple infections of 7 hr. duration (apparently composed entirely of fourth-stage larvae) did not produce significant immunity. Significant immunity was produced by single infections of 72 or 96 hr. duration. It is concluded that the fourth-stage intestinal larvae (7 hr.) and larvae of the fourth-moult stage (48 hr.) are not the most important sources of the immunizing antigen in a T. spiralis infection.

7380 CARCINOMA OF THE PAROTID GLAND. (E.) Baker, R. R. (Johns Hopkins U. Sch. Med., Baltimore, Md.), P. M. Leand and W. M. Shelley. Arch. Surg. (Chicago) 92(6):868-871, 1966.

Of 38 patients with parotid gland cancer, 2 died of unrelated diseases within 5 yr. and 1 did not undergo surgery because of pulmonary metastases; the other 35 patients underwent radical parotidectomy with radical neck dissection (19 patients), parotidectomy with radical neck dissection (5 patients), or simple parotidectomy (11 patients). In 8 patients with high-grade mucoepidermoid carcinoma, the 5-yr. survival rate was 37%, but 1 of these 3 patients died with disease after 5.5 yr. Postoperative X-rays were admin. to 3 patients; 1 survived 5.5 yr., the others died within 2 yr. Of 12 patients with mid- or low-grade mucoepidermoid carcinoma, 11 survived 5 yr. The 5-yr. survival rate in 4 patients with adenoid cystic carcinoma undergoing wide radical surgery was 75%, but all but 1 of these patients later died with disease; another patient underwent parotidectomy only and was alive after 9 yr., having undergone wide radical surgery for a recurrence 2 yr. after local excision. One patient with anaplastic giant cell carcinoma died in the immediate postoperative period. Of 4 patients with malignant mixed tumors, 2 died of local recurrences within 5 yr. Radical surgery is indicated for patients with high-grade mucoepidermoid or anaplastic carcinomas. Mid- and low-grade mucoepidermoid carcinomas pursue a more benign course and can be managed by local excision without radical neck dissection. Three patients with glandular adenocarcinomas survived 5 yr. after conservative parotidectomy without sacrifice of the facial nerve, whereas 2 other

GENERAL

patients undergoing radical parotidectomy died of disease. Clinical signs of the more malignant tumors were pain in the region of the tumor, facial nerve palsies, and palpable cervical lymph nodes.

- 7381 SURGICAL ASPECTS OF HENOCHE-SCHÖNLEIN'S PURPURA. (E.) Lindenauer, S. M. (U. Michigan Med. Ctr., Ann Arbor) and E. S. Tank. Surgery 59(6):982-987, 1966.

Between 1954-1964, 36 children under 5 and 14 adults over 17 (av. age 45 yr.) with Henoch-Schönlein's anaphylactoid purpura were seen. Abdominal pain with nausea and/or vomiting was present in 39 patients; 16 showed gastrointestinal bleeding, but this was not massive in any case. Retroperitoneal and subserosal bleeding was present in 4 cases. Exploratory surgery was performed in 7 patients, revealing intussusception in 3 patients (of the jejunum in 2 cases, of an unspecified site in 1); these patients underwent resection of the involved area. In the other 4 patients, no surgical lesion was found; the operation had no adverse effect on the course of disease. There were no operative deaths. One case history is given, of a 5-year-old boy with simultaneous intussusception and spontaneous perforation of the ileum. This patient was the only one of 17 who had responded to previous steroid therapy (hydrocortisone). A survey of the literature (19 references) showed about 50 cases of intestinal intussusception complicating Henoch-Schönlein's purpura, with a mortality rate of 55% in 11 patients not undergoing surgery and of 13% in 39 operated patients (all deaths occurred in patients operated on before 1940); there were also 4 cases of spontaneous perforation, all fatal.

- 7382 ENZYME HISTOCHEMISTRY OF ACUTE STAPHYLOCOCCAL ENTEROTOXIN GASTROENTERITIS IN RHESUS MONKEYS. (E.) Kent, T. H. (Walter Reed Army Inst. Res., Washington, D. C.), H. R. Jervis and J. G. Kuhns. Am. J. Path. 48(4):667-681, 1966.

Rhesus monkeys (Macaca mulatta) developed acute gastroenteritis after admin. of purified staphylococcal enterotoxin B (150 µg by gastric tube). The lesion was max at 4-8 hr. and rapidly regressed 12-72 hr. after enterotoxin admin. Sequential changes in mucosal enzyme activity correlated well with the development and regression of the lesion. When the lesion was greatest, gastric mucus secretory cells were distended and then depleted and the chief cell cytoplasm appeared shrunken. At the same time, enzyme activity decreased in the surface mucous cells and acid phosphatase activity increased slightly in chief cells. Parietal cells changed neither in appearance nor activity. The small intestine showed diffuse epithelial degeneration and sloughing, shortening of the villi and lengthening of the crypts, together with strong depression of alkaline and acid phosphatase, glucose-6-phosphatase, and the hexokinase and oxidative systems. Jejunal mucosa was severely depleted of lipid droplets, while a prominent increase was seen in epithelium and lamina propria.

- 7383 THE EFFECTS OF CHRONIC PROTEIN DEFICIENCY IN RATS. II. BIOCHEMICAL AND ULTRASTRUCTURAL CHANGES. (E.) Svoboda, D. (U. Kansas Med. Ctr., Kansas City), H. Grady and J. Higginson. Lab. Invest. 15(4):731-749, 1966.

After 104 or 232 days of protein deprivation, ultrastructural changes were seen in the liver, pancreas, heart, and adrenals of rats. Gross atrophic changes and marked wt. loss were also noted; after 2 wk. of realimentation the organs, especially spleen and thymus, showed marked recovery. Ultrastructural changes in the livers of protein deficient rats included diminution of rough endoplasmic reticulum, nucleolar enlargement, nuclear clefts, lipid accumulation, swelling and distortion of the mitochondria and glycogen accumulation. The pancreas showed atrophy, mitochondrial abnormalities and loss of zymogen granules, but only slight changes in the rough endoplasmic reticulum and ribosomes. Slight degenerative and atrophic changes were seen in the heart. The adrenal zona fasciculata showed enlargement and partial dissolution of the limiting membranes of the mitochondria. No significant jejunal lesions were noted, but electron-dense material was seen between the cells. The signs of focal cytoplasmic degradation and necrosis were minimal in all organs studied, indicating cellular adaptation rather than irreversible injury; there were no lesions common

to all organs. Total liver RNA, protein, and mitochondrial protein decreased markedly; the decreases in mitochondrial protein and glutamate dehydrogenase in the liver showed that the mitochondria were very sensitive to protein deficiency. The changes observed were different from those produced by inanition. The relationship of these lesions to human kwashiorkor is discussed.

- 7384 ANTIBODY-DEFICIENCY SYNDROME WITH EXUDATIVE ENTEROPATHY AND UNUSUAL ERYTHROCYTE ANTIBODIES. (Ger.) Strohmeyer, G. (U. Hamburg, Germany), K. Havemann, F. Petersen and H. H. Hoppe. Schweiz. Med. Wschr. 96(18): 590-597, 1966.

A 43-year-old man with a 25-yr. history of recurrent bronchial, pulmonary and gastrointestinal, bacterial infections was found to be suffering from an acquired, idiopathic antibody-deficiency syndrome, hypogammaglobulinemia and a protein-losing gastroenteropathy with hypoproteinemia and nocturnal edema of the legs. Studies with radioactive γ -globulin and sternal puncture confirmed that hypogammaglobulinemia was due to decreased synthesis of γ -globulin (approx. 20% normal) in the absence of plasma cells in the bone marrow. Monothermic cold hemolysin was demonstrable in the undiluted plasma, although the cold-agglutination titer was normal. Treatment by i.m. inj. of γ -globulin improved the clinical condition and reduced the frequency of infections without inducing a significant elevation of the level of serum γ -globulin. Occasional, strong anaphylactic reactions to inj. may have been due to the patient's demonstrated formation of sessile antibodies of the tuberculin type.

- 7385 REPORT OF A RARE DISEASE SYNDROME CAUSED BY A PANCREATIC ADENOMA. (Ger.) Zenker, R. (U. Munich, Germany), M. M. Forell and R. Erpenbeck. Deutsch. Med. Wschr. 91(14):634-636 & 639-640, 1966.

Over a period of 2 1/2 yr., a 46-year-old woman was subject to recurrent episodes of severe, intractable diarrhea, at intervals of 1-4 mo., accompanied by considerable diminution of serum potassium, circulatory hypotonia, and itching exanthemata similar to those seen in urticaria. An abrupt worsening of the condition was accompanied by a serious loss of potassium, sodium, calcium and chlorine via the stools, and by extreme hypokaliemia. Operation confirmed the presence of a non-insulin-producing adenoma of the pancreas, whose excision was followed by complete normalization of laboratory findings and disappearance of symptoms. The authors conclude that the patient was suffering from a Priest-Alexander-Verner-Morrison variant of the Zollinger-Ellison syndrome.

- 7386 CIRCULATORY AND METABOLIC ALTERATIONS ASSOCIATED WITH SURVIVAL OR DEATH IN PERITONITIS: CLINICAL ANALYSIS OF 25 CASES. (E.) Clowes, G. H. A., Jr. (South Carolina Med. Coll., Charleston), M. Vucinic and M. G. Weidner. Ann. Surg. 163(6):866-885, 1966.

Serial hemodynamic and metabolic studies were made of 25 patients during the course of fulminating peritonitis secondary to a ruptured viscus. The course of significant changes is detailed separately for those who made prompt recoveries, those with delayed recoveries, those who died within a short time and those who died only after prolonged peritoneal infection. In general, as edema and ascites developed, hypovolemia and electrolytic imbalances were accompanied by cardiac indices well below the normal resting value, incipient metabolic acidosis and lacticidemia. When the cardiovascular system was capable of responding, this was followed by elevated cardiac indices, generally elevated metabolic rate, much-increased caloric expenditure and increased respiratory effort. When such a high degree of cardiac output could not be sustained or could not be developed, metabolic acidosis, lacticidemia and bacteremia all increased rapidly, contributing further to inadequate venous return. There was a rapid, further increase of caloric expenditure, exhaustion of the sources of energy (e.g., stored fats and proteins) and elevation of central venous pressure just prior to the onset of terminal heart and respiratory failure. Several illustrative case histories are cited and the rationale of treatment is discussed in some detail.

- 7387 EARLY ENDOSCOPIC DIAGNOSIS IN UPPER GASTROINTESTINAL HEMORRHAGE. AN ANALYSIS OF 323 CASES. (E.) Hedberg, S. E. (Harvard Med. Sch., Boston, Mass.). Surg. Clin. N. Am. 46(3):499-512, 1966.

GENERAL

Among 323 patients presenting in emergency status with overt or suspected upper gastrointestinal hemorrhage, accurate differential diagnosis was achieved in 92% of those undergoing endoscopy within 24 hr. and in 81% in whom endoscopy was postponed or deferred until after radiography. (In the latter group, the mortality rate for non-variceal hemorrhage was increased from 5.5-19.0%.) Comparative percentages of successful differential diagnoses, as confirmed at the time of operation are given for X-ray alone, endoscopy alone and X-ray + endoscopy among 155 patients going to surgery, as follows: 61, 88 and 96, resp. Similar tabulations in terms of the final, established diagnoses are given for 93 massively bleeding patients (47, 83 and 87, resp.) and for 51 of 93 who underwent immediate endoscopy + X-ray at the time of admission (51, 86 and 92, resp.). Endoscopy entailed no fatal complications. Non-fatal complications occurred in 2.4% of the endoscoped group, including laceration or bruising of the pharyngeal mucosa, perforation of the esophagus (during esophagoscopy) and one perforation of the stomach due to faulty technic. Two fatalities occurred: 1 due to uncontrollable hemorrhage from the sites of previous gastrotomy and laparotomy incisions in a patient referred for uncontrollable bleeding from gastroscopic biopsy sites, 1 due to coronary thrombosis in a patient with two previous myocardial infarcts. The author concludes that immediate endoscopy + X-ray, permitting exact localization of bleeding points in the stomach or esophagus, is indicated in the examination of patients presenting with overt or suspected, massive gastrointestinal bleeding.

- 7388 THIABENDAZOL IN THE TREATMENT OF HELMINTHIASIS. (Ger.) Asshauer, E. (Bernhard-Nocht Inst., Hamburg, Germany) and W. Mohr. Arzneimittelforschung 16(3):428-431, 1966.

A total of 52 adults suffering from infestation by 71 different types of worm were treated with 2-(4'-thiazolyl)-benzimidazole (thiabendazole). Only 9 patients were suffering from such infestations alone, and 22 received routine medications for malaria, amebiasis, schistosomiasis, filariasis or other protozoan infections intercurrently. The drug proved highly effective against Ancylostoma duodenale and braziliense, Ascaris lumbricoides, Strongyloides stercoralis and Trichostrongylus; considerably less effective against Trichuris trichiura and ineffective against Taenia saginata or solium. The drug was also moderately effective against hookworm. Side effects were seen in approx. one of three patients, consisting of vertigo, nausea, exhaustion, headache and/or disturbance of vision. In one patient, the drug appeared to induce or precipitate a psychotic episode requiring psychiatric hospitalization, although a true drug psychosis could not be established definitely.

- 7389 DEMONSTRATION OF PATHOGENIC ACTIVITY IN MAN OF A Leishmania STRAIN ISOLATED FROM Arvicanthis niloticus IN PIROUNDRY (SENEGAL). SELF INOCULATION AND OBSERVATION. (Fr.) Ranque, P. (40 Farges St., Marseille, France) and P. Camerlynck. C. R. Acad. Sci. (Paris) 262(6)(Ser. D):664-665, 1966.

Self-inoculation with a culture of Leishmania in the leptomonad stage (via intradermal inj. on the surface of the thigh) induced a typical case of cutaneous Leishmaniasis, confirmed at 90 days by biopsy demonstration of a granuloma containing Leishmaniae. The culture employed was derived originally from the spleens of rodents of the species Arvicanthis niloticus which had been sent from Senegal, where the disease is prevalent. It was the first demonstration that this animal may be a significant etiologic factor in the spread of the disorder. Three additional strains were isolated later from rodents of the same species, which were captured in another village in which 3 cases of cutaneous Leishmaniasis had been found and in which 21 of 52 inhabitants showed positive reactions to an intradermal test for the presence of the organism.

ESOPHAGUS

- 7544 RESULTS OF RADIOTHERAPY IN 1000 CASES OF ESOPHAGEAL CANCER. (Rum.)
Ruderman, A. I. (Cent. Inst. Med. Spec., Moscow). Oncol. Radiol. 4(3):
229-234, 1965.

Experience with radiotherapy in the treatment of 1000 patients with cancer of the esophagus from 1946-1964 is discussed. Noncomparability of the number and stage of the various types of cancer handled by the various technics utilized (static and mobile X- or gamma-irradiation, sometimes supplemented by intracavitary irradiation) forbids comparative evaluation of specific approaches, but certain general conclusions can be drawn. Successful tumor destruction was observed most often with a total absorbed dose of around 6000-8000 rad, and sometimes, too, with smaller doses (3000-4000 rad). In other instances, larger doses (up to 10,000 rad) failed to destroy all tumor elements. Irrespective of the type of cancer and technic of irradiation, the most suitable length of a treatment cycle is 6-8 wk. A whole cycle was completed by 79% of the patients. In terms of immediate results, clinical recovery (defined as complete regression of clinical and radiologic signs of cancer) was achieved in 35%, and a palliative effect, in 39%; radiotherapy was ineffective in 26%. Of the "clinically recovered" patients, 28% survived for 2+ yr., 16% for 3+ yr., 6% for 4+ yr., and 4% for 5+ yr. Although 30% of the patients died from various causes which could not be related to the esophageal malignancy, it cannot be ruled out that some deaths from cardiovascular and pulmonary causes may have been related to the admin. of massive doses of radiation.

- 7545 EXPERIMENTAL STUDY OF POSTOPERATIVE DYSPHAGIA IN CASES OF ATRESIA OF THE ESOPHAGUS. PRELIMINARY STUDY. (Fr.) Desjardins, J. G. (St.-Justine Hosp., Montreal, Canada) and M. D. Tassé. Un. Med. Canada 95(5):598-600, 1966.

The effect of surgical trauma on esophageal function was studied in a group of dogs subjected to various surgical technics used in the clinical management of congenital atresia of the esophagus. In 7 dogs subjected to esophageal resection with end-to-end anastomosis, no esophageal pathology or changes in peristaltic activity were observed. Similar normal response occurred in 11 dogs subjected to a 2-3-cm circular myomectomy. In 13 animals subjected to complete excision of the esophagus, marked dysphagia with regurgitation and vomiting was observed; normal peristaltic waves were replaced by localized, simultaneous contractions of reduced amplitude; av. intra-esophageal pressure was 16.2 mm Hg as compared to preoperative values of 25-35 mm Hg; at autopsy, the esophagus was markedly dilated. In 7 dogs subjected to cervical vagotomy or resection of the esophageal branches of the vagus nerve, marked dysphagia with cough and vomiting was observed; no normal peristaltic activity in response to deglutition occurred; contractions were segmentary, localized, spasmodic, and ineffective. Results suggest that the trauma of surgery is responsible for the post-operative changes in esophageal function observed in children with atresia subjected to esophageal reconstruction.

- 7546 CARCINOMA OF THE OESOPHAGUS WITH TYLOSIS (KERATOSIS PALMARIS ET PLANTARIS). (E.) Shine, I. (U. Hawaii, Honolulu) and P. R. Allison. Lancet 1(7444):
951-953, 1966.

The case is reported of a 61-year-old man in whom tylosis was found shortly after removal of a squamous cell carcinoma localized at the site of an esophageal stricture. The patient had had difficulty swallowing throughout his life. Sliding hiatus hernia, gastric-lined esophagus, and reflux esophagitis were also present. The propositus' mother was thought to have had tylosis and dysphagia; of his 3 children, 1 had tylosis and dysphagia due to esophageal stricture which was corrected at surgery, 1 had tylosis but no evidence of dysphagia, and 1 was too young (1 yr. old) to manifest any abnormality. Tylosis appears to be determined by a single autosomal gene in the heterozygous state.

- 7547 ESOPHAGEAL MOTILITY IN SYSTEMIC LUPUS ERYTHEMATOSUS, RHEUMATOID ARTHRITIS, AND SCLERODERMA. (E.) Tatelman, M. (Wayne State U. Sch. Med., Detroit, Mich.) and M. K. Keech. Radiology 86(6):1041-1046, 1966.

Esophageal motility was studied radiologically in three groups of patients with various connective tissue disorders, including 29 with scleroderma, 27 with proved

ESOPHAGUS

systemic lupus erythematosus, and 27 with long-standing rheumatoid arthritis. Complete lack of normal esophageal peristalsis was found in 20 of the 29 cases of progressive systemic sclerosis (scleroderma); in 4 patients with systemic lupus erythematosus esophageal peristalsis was slightly decreased. Esophageal motility was normal in all 27 cases of rheumatoid arthritis. Only 45% of the scleroderma patients with esophageal aperistalsis had ever experienced dysphagia, and in no case of systemic lupus erythematosus with lesser degrees of esophageal abnormality was there dysphagia. The apparent close relationship of esophageal aperistalsis and Raynaud's phenomenon, especially in those patients exhibiting resorption of the ungual tufts, is emphasized. The possibility that the two abnormalities have a common pathyophysiologic basis is briefly discussed. The interrelationship between esophageal aperistalsis or atony and scleroderma is emphasized; it is suggested that the patients with systemic lupus erythematosus who show less striking changes in esophageal motility may later develop scleroderma.

- 7548 EXPERIMENTAL USE OF DACRON AS AN ESOPHAGEAL PROSTHESIS. (E.) Schuring, A. G. (Ohio State U. Hosp., Columbus) and J. W. Ray. Ann. Otol. 75(1): 202-207, 1966.

A dacron tube, preclotted with the animal's own blood, was implanted into dogs as a prosthesis to replace a 4-6-cm segment of the cervical esophagus. All grafts sloughed, passing into and through the digestive tract, within a few wk.; at that time, the excised areas had been replaced by a fibrous wall lined with mucosa in all animals. All of these segments became stenotic, the fibrosis progressing to nearly complete obstruction, but some animals were maintained on soft or liquid diets for 10 mo. The passages could have been maintained by early and regular dilatation after the dacron tubes sloughed, but this was not done in these animals. There were no wound infections, fistulas, or complications from impingement on surrounding structures.

- 7549 SIMULTANEOUS CINERADIOGRAPHIC-MANOMETRIC STUDY OF THE DISTAL ESOPHAGUS: SMALL HIATUS HERNIAS AND RINGS. (E.) Heitmann, P. (Mt. Sinai Hosp., New York, N. Y.), B. S. Wolf, E. M. Sokol and B. R. Cohen. Gastroenterology 50(6):737-753, 1966.

In the presence of a small hiatus hernia, the supradiaphragmatic esophageal pouch had 2 functionally distinct compartments, the upper portion (vestibule) with sequential contractile motor activity during swallowing, and the lower portion (the true hernial sac) being inactive. A weblike ring (Schatzki) or notches often appeared at the junction of these segments; no peristaltic activity was present at or below this ring. A broad ring with contractile behavior ("contractile A-ring") was sometimes present; it showed resting high pressure that fell upon swallowing, which differed from the normal resting high pressure zone in being shorter in length and showing an abrupt, not gradual, transition to contiguous pressures. If this ring was present, there was no retrograde barium flow from the hernial sac into the tubular esophagus. Patients without a resting high pressure zone showed barium reflux, which was delayed so long as peristalsis persisted in the vestibular segment. The location of the pressure inversion point was variable.

- 7550 THE NATURAL HISTORY OF HAEMORRHAGE FROM OESOPHAGEAL VARICES. (E.) Hislop, I. G. (Cent. Middlesex Hosp., London, N. W. 10), T. E. Waters, T. D. Kellock and B. Swynnerton. Lancet 1(7444):945-948, 1966.

Among 6,175 cases of upper gastrointestinal hemorrhage selected at random at 2 general hospitals, hemorrhage was attributable to portal hypertension from cirrhosis in less than 3%. Among 63 patients admitted for their first episode of hemorrhage, 34 deaths (54%), all directly or indirectly attributed to hemorrhage, were observed. Three deaths occurred among 9 patients subjected to emergency surgery for the purpose of arresting hemorrhage or preventing recurrence, while 31 deaths occurred without surgery. Mortality rate was higher in men and in the elderly. Of 23 patients who survived the initial admission without an operation, 17 further deaths had occurred at 5 yr. Seven patients subsequently underwent elective surgery; 1 was alive at 5 yr. Sixteen patients had no surgery within the next 5 yr.; 10 died

ESOPHAGUS

hepatic causes, 2 of causes unrelated to the liver; and 4 survived the period. These 4, 3 subsequently died of causes unrelated to the liver. Thus, of the original 63 patients admitted, there were only 4 survivors at the time of final review, of whom only 1 had not had an operation.

- 51 CARCINOMA OF THE ESOPHAGUS. A TWENTY YEAR STUDY. (E.) Pinch, L. W. (Bryn Mawr Hosp., Pa.), K. H. Christiansen and W. C. Stainback. Am. J. Surg. 111(5):704-707, 1966.

Cancer of the esophagus was diagnosed in 57 patients (46 men and 11 women; av. age 57 yr.) from 1945-64. Presenting complaints, methods of diagnosis, and characteristics of the disease are discussed. Av. survival was 2 mo. in 19 untreated patients; 5.7 mo. in 19 and 7 yr. in 1 patient treated by X-rays; 3.6 mo. in 12 patients (2 others were lost to follow-up) treated by resection; 14 mo. in 2 patients treated by resection and X-rays. Operative mortality in 16 patients treated by esophagogastrectomy was 50%; this was attributed to several factors including small tumor loads, advanced age of patients, extensiveness of surgery, poor nutrition, and perhaps poor preoperative selection of patients. It is concluded that X-ray therapy gave the best palliation in most cases and that surgical resection for cure should be used only in the most suitable patients.

- 52 TUMOR CELLS IN THE THORACIC DUCT LYMPH IN CARCINOMA OF ESOPHAGUS AND CARDIA OF STOMACH. (E.) Ku, Y.-C. (Peking Coll. Med., China) and C.-C. Chang. Chin. Med. J. 85(4):258-263, 1966.

Histological investigation of thoracic duct lymph in 22 patients subjected to left thoracotomy for cancer of the esophagus or cardia revealed the presence of single tumor cells and/or clusters of tumor cells in 9 patients. No direct tumor invasion of the thoracic duct or cisterna chyli was observed. Among 10 survivors of radical resection, 3 died at 8, 9, and 21 mo., resp., and none had tumor cells in the thoracic duct lymph; of 7 other patients alive and well after 1-2.5 yr., 3 patients had positive tumor cells in the thoracic duct lymph. The clinical significance of the presence of tumor cells in thoracic duct lymph is discussed. Factors influencing the occurrence of tumor cells in thoracic duct lymph are reviewed. Surgical manipulation of the tumor area may cause the entry of tumor cells into the thoracic duct and then into the blood stream, in which case ligation of regional blood vessels during tumor surgery will not entirely block the route of dissemination through the blood stream.

- 53 PHARMACORADIOGRAPHIC STUDIES OF THE ESOPHAGOGASTRIC REGION IN AN EFFORT TO DEMONSTRATE THE EXISTENCE OF SMALL HIATUS HERNIAS. (PRELIMINARY RESULTS OF TESTS OF CG-201 GRÜNENTHAL.) (Ger.) Longin, F. (U. Würzburg, Germany). Fortschr. Roentgenstr. 104(3):389-398, 1966.

In a group of patients in whom conventional contrast radiography failed to confirm or disprove the existence of small hiatus hernias in the esophagogastric region, suspected because of anomalies observed during routine examination, preadmin. of CG-201 (a relatively new spasmolytic agent undergoing clinical testing) permitted confirmation of the condition in 52%, exclusion of the condition from consideration in 12%. The drug is said to simultaneously induce spasmolysis, increased tonus of the esophageal sphincter and increased tonus of the cardia.

- 54 HISTOPATHOLOGICAL STUDIES ON THE ESOPHAGUS OF NEWBORN INFANTS. (Jap.) Matsumoto, Y. (Osaka City U. Sch. Med., Japan). Osaka Shiritsu Daigaku Igakubu Zasshi (J. Osaka City Med. Ctr.) 14(7-9):309-341, 1965.

Histopathologic studies were made of the esophagus of 250 stillborn and live-born infants autopsied during the past 5 yr. The mucosal epithelium from full-term infants showed differentiated zones much as seen in the squamous epithelium of the adult. The submucosa showed many fully developed esophageal glands. Ciliated epithelium was detected in the esophagus of 20.8% of the infants and was more frequent in prematurely born infants. With reference to cardiac glands, 10.4% were ectopic; there was no significant relation between the frequency of these ectopic glands and the period of survival. Congestion of the esophagus was frequent in

ESOPHAGUS

full-term infants which survived 4-7 days. Submucosal hemorrhages were seen frequently in infants which died within 24 hr., but no relation to birth wt. was apparent. Sixty of 250 cases showed esophagitis which was of 5 types. Neonatal esophagitis was assumed to be more frequent among full-term babies and those with congenital anomalies of the digestive organs. Sixteen cases of esophagitis showed ulceration which was frequent in the lower portion and was also likely to be multiple.

- 7555 BLEEDING ESOPHAGOGASTRIC VARICES. AN ENDOSCOPIC STUDY OF 50 CASES. (E.) Dagradi, A. E. (VA Hosp., Long Beach, Cal.), S. J. Stempien and L. K. Owens. Arch. Surg. (Chicago) 92(6):944-947, 1966.

A 5-grade classification for esophageal varices is presented. Endoscopic examination of 50 patients with bleeding esophagogastric varices showed that the lesions were all extensive and the highly developed category (Grade 4 to 5). The source of bleeding was located in the distal 5 cm of the esophagus in 86% of cases. Bleeding from esophageal varices was always readily controlled by a balloon tamponade. Actively bleeding gastric varices were noted in 15 patients; all showed a highly developed esophageal collateral venous plexus, but no esophageal bleeding source was noted. Varices of Grades 4 and 5 were seen in the distal 8-17 of the esophagus in 11 of these patients; the other 4 showed Grade 3 to 4 varices in the distal 12-17 cm of the esophagus. The site of active bleeding was the upper posterior wall of the fundus in 5 cases, the cardia in 5, and just below the esophagogastric junction in 13. Balloon tamponade was less successful in controlling bleeding from gastric varices than from esophageal varices. Vasopressin did not control bleeding if tamponade failed to do so. Three patients developed recurrent bleeding from persistent, large esophagogastric varices despite a portacaval shunt; all died, and autopsy showed occlusion of the venovenous anastomosis in all cases. Only 2 mild cases of esophagitis were noted in the entire group, but 32 of 45 patients examined (71%) showed sliding hiatus hernias.

- 7556 CYTODIAGNOSTIC EXAMINATION OF THE ESOPHAGUS. (Dan.) Naess-Schmidt, T. E. P. A. Poll and P. Bach-Nielsen. Ugeskr. Laeg. 128(20):589-591, 1966.

A new procedure for obtaining material from the esophagus to be used for cytologic study is described in detail. Results are said to be more reliable than those obtained by X-ray or endoscopy, with patients subjected to only 10-15 minutes' examination time. (13 references)

STOMACH

- 7607 MYOCARDIAL INFARCT IN GASTRECTOMIZED PATIENTS. (Ger.) Mörl, H. (St. George Hosp., Leipzig, Germany) and J. Venzmer. Virchow. Arch. Path. Anat. 341(1):79-84, 1966.

The male:female ratio was 4.1:1 among 612 autopsied patients who had undergone gastric surgery at some time or other. Little or no significant coronary sclerosis was seen in 61.2% of the males; moderate to moderately severe coronary sclerosis in 28.0% and severe, stenosing coronary sclerosis in 10.8%. Comparable tabulations for females were 78.8%, 16.8% and 4.4%, resp. When severe coronary sclerosis did occur, its onset was delayed by approx. 10 yr., as compared to a much larger autopsied group as a whole. The more severe degrees of sclerosis occurred significantly less frequently among patients undergoing gastric surgery prior to 50 yr. of age. Fatal myocardial infarcts were sustained by only 2.77% of the group with a history of gastric surgery (with a male:female ratio of 16:1), as compared to 6.34% of all autopsied patients. In all, 66% of the patients with a history of gastric surgery were significantly underweight, and a significant relationship between being underweight and hypotensive and protection from coronary sclerosis and/or myocardial infarct was demonstrable.

- 7608 THE IMPORTANCE OF PARIETOGRAPHY IN ASSESSMENT OF THE OPERATED STOMACH. (Rus.) Rozenshtaukh, L. S. (Roentgen.-Radiol. Res. Inst., Min. Health, RSFSR, Moscow), N. U. Shniger and N. M. Pushkareva. Khirurgia (Moskva) 42(3):21-24, 1966.

In order to evaluate the condition of the gastric stump after Billroth-II operation the authors resorted to parietography in 28 cases (age 33-60 yr.). In 15, surgery was due to cancer, in 7 due to polyps and in 6 due to ulcer. In 26 patients the investigation proved to be effective and painless; in one case the establishment of pneumoperitoneum was attended by short-term pain and in one instance it was ineffective. For the investigation it is sufficient to introduce 1,000-1,200 ml of oxygen into the abdominal cavity. The stomach is distended with the aid of a thin tube. The employment of gas-forming mixtures and saturators is not recommended. The authors studied the parietographic picture of the gastric stump in health, as well as in tumors of diverse localization. Parietography is a valuable additional method of investigating the operated stomach; it enables one to diagnose cancer, to establish tumor size and spread, and its interrelations with the surrounding organs and tissues. These data are of paramount importance for deciding on the problem of the possibility of a repeated operation. Two case histories are given in some detail.

- 7609 THE METHODS OF STUDY OF THE GASTRIC WALL STRUCTURE IN CANCER. (Rus.) Sigal, M. Z. (Lenin State Inst. Postgrad Med. Train., Kazan, USSR) and S. M. Perlin. Vop. Onkol. 12(4):3-9, 1966.

With an extension and expansion of a method described previously, the authors studied the structure of the gastric wall in 110 subjects undergoing surgery for cancer (83), ulcer (23), or polyps (4). The technics included transillumination observations during operations and on surgical specimens, and cytologic studies on the laminar topography of pathologic foci by a procedure the authors call "non-penetrating gastrotomy." In 16 cases, angioscopic study of surgical specimens was collated with the angiographic findings. The multiple forms assumed by cancerous growths examined with the technics described are illustrated here and contrasted with the pictures obtained in noncancerous gastric lesions.

- 7610 ELECTROPHORETIC AND IMMUNOELECTROPHORETIC STUDY OF THE PROTEIN COMPOSITION OF THE INTESTINAL JUICE FOLLOWING STOMACH RESECTION IN DOGS. (Rus.) Pushkarev, A. S. (Lunacharskii Inst. Med., Astrakhan, USSR) and A. V. Afanasieva. Biull. Eksp. Biol. Med. 61(3):39-43, 1966.

The results of an electrophoretic and immunoelectrophoretic analysis of the intestinal juice in 9 dogs before and after resection of two-thirds of the stomach are presented. Four protein fractions are electrophoretically determined as constituent of the intestinal juice (intestinal loop was isolated after Thiry-Vella). Three of

TOMACH

hem had globulin mobility, and one had albumin mobility of blood plasma. A/G index of the intestinal juice was less than 1. The secretion during the first days after gastric resection showed no essential changes; however, it increased 1.5 times after 1 yr. Following stomach resection, the total protein content of the intestinal juice did not change substantially, the albumin concentration decreased, while that of alpha- and beta-globulins showed an increase. A/G index decreased. These changes persisted after 1 yr. The intestinal juice contains antigenic components characteristic of the normal dog blood serum. Gastric resection caused no significant changes in the amount of serum proteins. The phenomenon of complete identity of the antigenic structure of blood serum and intestinal juice proteins may be evidence in favor of I. P. Razenkov's on the possibility of discharge of serum proteins into the cavity of digestive tract.

- 611 TEN CASES OF EARLY GASTRIC CANCER. (Jap.) Hyodo, H. (Kochi Nat. Hosp., Japan), K. Takashima, S. Kakiuchi, S. Nomachi, T. Okura, T. Sunami, E. Sakai, Y. Nozu, Y. Tadatomo and S. Oshima. Iryo (Therapeut. [Tokyo]) 19(11):1004-1023, 1965.

Among 2,600 fluoroscopic examinations of the stomach performed in 1964, diagnosis of early gastric carcinoma was made in 15 patients. Of these, cancer cell infiltration was observed in the mucosal layer in 9 and in the submucosal layer in 6 patients. Radiological, histological, and macroscopic findings are reported for 10 of the above patients as well as for 1 patient with subserosal infiltration and 1 patient with a recent ulcer and ulcer scar. X-ray findings are compared in patients with early gastric carcinoma with an excavated and/or eroded or elevated surface. The advantages of the rolling technic for visualization of the gastric antrum and of the first oblique position in examinations of the cardia, lower cardia, and posterior stomach wall are discussed. Various other radiological technics are described.

- 612 DEMONSTRATION OF SUGARS DERIVED FROM GLYCOPROTEINS IN THE GASTRIC SECRETIONS OF SUBJECTS WITH NORMAL GASTRIC MUCOSA AND IN PATIENTS WITH CHRONIC GASTRITIS. (Ger.) Berg, G. (U. Erlangen-Nürnberg, Germany), H. D. Groben, K. Heinkel and N. Henning. Zschr. Klin. Chem. 4(3):108-111, 1966.

Among 13 patients with chronic gastritis, a tendency toward increased content of amino sugars in fasting gastric secretions was demonstrable by paper chromatography, following hydrolysis with ion-exchange, sulfonic resins ("permutit"). The controls were 9 patients with histologically-verified, normal gastric mucosa. With respect to other sugar components, there were no significant differences between the 2 groups. Glucuronic acid could not be demonstrated by the method employed. The authors comment on the need for improved methods of analysis.

- 613 CANCER OF THE STOMACH. RESULTS OF SURGICAL TREATMENT. (Dan.) Zacho, A. and K. Fischermann. Ugeskr. Laeg. 128(20):583-589, 1966.

Among 561 patients hospitalized for gastric surgery during a 16-yr. period, 14% were rejected as inoperable, 30% proved inoperable upon exploratory laparotomy, 2% were treated by intubation or anastomosis alone, and the tumor-bearing area was resected in 44% (248 patients), although resection was palliative, rather than radical in approx. one case in four. A total of 142 patients survived the first postoperative yr., with 2 of these lost to subsequent follow-up. Five-yr. survivals among the 140 who could be followed were 9% when surgery was palliative, 41% when it was radical, 47% in the absence of metastasis and 12% in the presence of metastasis. Comparable tabulations for patients (52) surviving total gastrectomy were 2%, 26%, 40% and 6%, resp.; for patients (51) surviving upper gastric resection, they were 9%, 38%, 56% and 10%, resp.; for patients (37) surviving lower gastric resection, they were 13%, 69%, 50% and 24%, resp.

- 614 MECHANICAL SUTURE BY SOVIET APPARATUS IN GASTRIC RESECTION: USE IN 4,000 OPERATIONS. (E.) Gritsman, J. J. (Inst. Exp. Surg. Apparatus-Instruments Res., Moscow). Surgery 59(5):663-669, 1966.

The technic is described for closure of the gastric stump following resection using the gastric stump apparatus, an apparatus for placing gastrointestinal anastomosis,

STOMACH

and mechanical suturing by means of a double row of tantalum staples. After reviewing results obtained with this method in experimental studies, the author presents comparative data on resection for gastric cancer and ulcer using the manual and mechanical suture. According to data published by 62 surgeons from many countries using manual suture, the mortality rate was 3.2% following 42,528 resections for ulcer and 10.4% after 10,358 resections for cancer (with no total gastrectomies). The prevailing complication was peritonitis caused by leaks in the suture lines; the leading cause of death was technical imperfection of operation. From data of approx. 4,000 resections performed with mechanical suture, 1,663 cases were selected for analysis. Mortality rate was 1% among 958 resections for ulcer and 3.6% among 668 resections for gastric cancer. Overall mortality was 4.4% among 52,886 resections with manual suture and 2% among 1,663 resections with mechanical suture. The significance of results was determined after calculation of mortality index fluctuation limits according to the tables of A. I. Boiarsky. Among the 4,000 instrumental operations, suture line incompetence was observed in only 0.3%. Among cancer patients subjected to resection and mechanical suture, follow-up after 4 yr. revealed a survival rate of 60%, considering the radical nature of the operation; recurrence of cancer in the gastric stump was rarely observed. Among ulcer patients, functional results at later dates were similar to and at times better than those seen after resection by the Finsterer technic. No pathological phenomena due to the presence of metal in the tissues were observed in either ulcer or cancer patients.

- 7615 CLINICAL STUDIES ON GASTRIC JUICE SECRETION. CORRELATION BETWEEN ENDOSCOPIC AND GASTROCAMERA FINDINGS AND GASTRIC SECRETION. (Jap.) Kudo, M. (Sapporo Coll. Med., Japan). Sapporo Igaku Zasshi (Sapporo Med. J.) 27(1-2):49-64, 1965.

Gastrocamera, gastroscopic, and secretion studies were performed in 928 patients with stomach diseases (atrophic or superficial gastritis, stomach ulcers, stomach carcinoma, etc.). The endoscopic findings were confirmed by histological examination of surgical or biopsy specimens. Similar studies were also performed in 286 normal subjects. Gastrocamera and endoscopic findings were sufficient to evaluate the degree of severity of lesions in the corpus and its mucosa, but were less accurate for pyloric lesions. The degree of atrophy of the gastric glands was correlated fairly well with the gastric juice components (mucoproteins, etc.) and the secretion vol. rate, before and after histamine stimulation. In atrophic gastritis, the secretion vol. rate was under 10 ml/15 min., with comparably low values for acidity and mucoprotein conc. but increased amounts of dissolved mucoproteose and of sialic acid in visible mucus. In superficial gastritis, a relative increased mucoproteose level was noted, but changes in the other components were less significant. Gastric secretion in patients with gastric ulcer or carcinoma depended upon the degree of coexisting gastritis. Gastric ulcer, however, was associated with relatively increased secretion rates and acidity, whereas these values were decreased in gastric carcinoma. This may reflect the different functional backgrounds of ulcers and carcinomas. If the lesions were located in the mucosa of the corpus, their severity was more closely correlated with secretion vol. rate, acidity, and mucoprotein conc. than with other components of the gastric juice.

- 7616 A STUDY ON GASTRIC EROSION IN TUMOR-BEARING RATS. (E.) Maekawa, A. (Nagoya City U. Sch. Med., Japan). Nagoya Med. J. 11(1):55-60, 1965.

Rats bearing Yoshida sarcoma and ascites hepatomas AH-13, AH-66, AH-66F, AH-130, AH-130F (strains G or N), AH-602, and AH-7974 were autopsied after they died of malignant disease. Gross and microscopic studies of the stomach, greater omentum, liver, spleen, lungs, adrenals, and kidneys were made. The frequency of gastric erosion varied from 1 tumor strain to another, being lowest with AH-130F (N) (16.7%) and AH-66 (11.1%), and highest with AH-130F (G), AH-7974, AH-130, and Yoshida sarcoma (74%, 50%, 58.3%, and 45.8%, resp.). The incidence of gastric erosion was greatest in those groups in which the av. wt. of the greater omentum (containing the pancreas) was largest; the increase in wt. of the greater omentum was proportional to the extent of invasion by the tumor. Gastric erosion probably occurred in the last stages of tumor growth. There was no age or sex difference in the incidence of gastric erosion. These lesions were frequently found along the plica epithelium of

TOMACH

the glandular stomach, but did not occur in the forestomach or duodenal mucosa; they were not usually infiltrated by tumor cells. Lung and adrenal metastases were frequent in animals with gastric erosion. When hepatomas AH-130F (G) and AH-130F (N) were transplanted into adrenalectomized rats, the frequency of gastric erosion was slightly, but not significantly, greater than in intact animals.

- 7617 ISOENZYMES OF LACTATE DEHYDROGENASE IN HUMAN GASTRIC MUCOSA AND GASTRIC CARCINOMA TISSUE. (E.) Baume, P. E. (Royal North Shore Hosp., Sydney, Australia), J. E. Builder, B. H. Fenton, L. G. Irving and D. W. Piper. Gastroenterology 50(6):781-786, 1966.

Electrophoretic analysis of gastric mucosa tissue demonstrated a pattern with predominance of lactic dehydrogenase isoenzymes 1, 2, and 3 in the fundus. Pyloric gastric mucosa and gastric carcinoma tissue (the 7 carcinomas were removed from the pylorus or the lesser curvature) consistently had identical isoenzyme patterns, predominantly isoenzymes 2, 3, and 4. The isoenzyme pattern characteristic of fundus mucosa extended very close to the histological junction between the mucosa of the pylorus and the corpus. The presence of gastritis did not affect the fundus mucosa isoenzymes. Lactic dehydrogenase levels were elevated in cancer tissue, but there was no qualitative abnormality in the production of lactic dehydrogenase enzymes in gastric carcinoma tissue. Statistically significant differences between the isoenzyme conc. of pyloric and fundus mucosa were obtained for isoenzymes 1, 3, and 5; significant differences between fundus mucosa and carcinoma were seen for isoenzymes 1 and 3.

- 7618 HYPOPHYSECTOMY AND GASTRIC RESTRAINT LESIONS. (It.) Cucinotta, U. (U. Messina, Italy). Riv. Pat. Clin. 20(1):43-47, 1965.

The effects of hypophysectomy on the development of gastric restraint ulcer were studied in 20 rats. Death occurred 6-12 hr. after treatment in 15 of 20 rats; no gastric lesions were observed; the remaining 5 rats showed restraint ulcers (4) or congestion (1). Controls subjected to hypophysectomy alone had no gastric lesions. Controls subjected to restraint alone all showed congestion and hemorrhage of the gastric mucosa, while 16 of 20 developed typical restraint ulcers; these animals survived longer (only 1 died 9 hr. after treatment) than those subjected to both restraint and hypophysectomy. Results indicate that, contrary to gastric lesions induced by pyloric ligation, restraint ulcers are not influenced by hypophysectomy.

- 7619 EVALUATION OF RECURRENCE IN GASTRIC ADENOCARCINOMA PATIENTS. (E.) Kuzma, J. W. (U. California, Los Angeles) and W. J. Dixon. Cancer 19(5):677-688, 1966.

The usefulness of recurrence as a measure of response in cooperative clinical trials was evaluated. Numerous shortcomings in using recurrence were encountered both because of the absence of reliable methods of evaluating recurrence, such as autopsies and biopsies, and because of the incomplete follow-up information which arises from irregular examinations or relocation of patients, attendance by numerous physicians, and the difficulties inherent in follow-up forms. In a review of 10 Gastric Adjuvant (thio-tepa) patients by 8 noted authorities in the field, sufficient disagreement existed in their evaluation to indicate that the use of recurrence as a response variable in data of clinical trials is open to serious question. A classification which permits 3 varying categories or certainties was drawn up. Upon application of this new method to 39 cases, recurrence rates ranging from 50% to 91% were obtained for the first 5 yr. for the 3 categories.

- 7620 STUDY OF PROTEOLYTIC ENZYMES OF THE STOMACH IN ACHLORHYDRIC PATIENTS. (Fr.) Hirsch-Marie, H. (Sci. Cancer Res. Inst., Villejuif), M. Conte and P. Burtin. Arch. Mal. Appar. Dig. 55(4):297-304, 1966.

Gastric proteolytic enzyme secretion was studied in 88 patients with achlorhydria ($\text{HCl} = 0$ or approx. 0 following histamine stimulation) in the course of gastritis, pernicious anemia, gastric cancer, chronic pancreatitis, or following gastrectomy. Secretion of proteolytic enzymes by the stomach was decreased in these patients both before (0-10 Tyrosine U and 0-0.3 Pepsin U as compared to 50-100 and 0.15-0.30, resp., in normal subjects) and after (0-20 Tyrosine U and 0-0.06 Pepsin U as compared to 180-300 and 0.51-1, resp.) histamine stimulation. Serum and plasma levels

STOMACH

(determined by acid hydrolysis of protein substrate at pH 2.0) showed a reduction from 220-500 Tyrosine U/ml/20 hr. and 0.7-1.65 Pepsin U/ml/20 hr. in normal subjects to 30-160 and 0.01-0.5, resp., in achlorhydric patients; however, the authors feel that this method is not specific enough to be of value. Gel- or immunoelectrophoresis revealed the presence of 1 or several of the 4 proteolytic enzymes previously identified in the gastric juice or extracts of normal gastric mucosa. Qualitatively, the characteristics of the proteases identified by gel- or immunoelectrophoresis were similar to the pepsinogens found in extracts of normal, nonactivated, gastric mucosa.

- 7621 EXPERIMENTAL STUDIES ON LYMPHATIC FLOW IN EACH LAYER OF THE GASTRIC WALL- IN VIEW OF METASTASIS IN GASTRIC CANCER. (Jap.) Sumiyoshi, Y. (Kyushu U. Sch. Med., Fukuoka, Japan). Fukuoka Igaku Zasshi (Fukuoka Acta Med.) 56(11):1071-1086, 1965.

Lymphatic flow was studied in the gastric wall of 41 dogs in an effort to determine whether or not lymph node metastasis was dependent upon the degree of penetration of the cancer in the gastric wall. Indigo carmine, india ink, chicken RBC, and lycopodium were inj. into the mucosa, submucosa, or muscle layer subserosa of the gastric wall, and the time required to reach the subserosal lymph nodes, along with other parameters, were compared for each of the inj. layers. The av. time required for indigo carmine and india ink to reach the subserosal lymph vessels was longest after inj. into the mucosa and shortest after inj. into the muscle layer subserosa. Chicken RBC (comparable in size to nuclei of small cancer cells) were more numerous in the regional lymph vessels after inj. into the muscle layer subserosa than after inj. into the other layers. More lycopodium (comparable in size to nuclei of large cancer cells) reached the regional lymph nodes after inj. into the muscle layer subserosa, less after inj. into the submucosa, and least after inj. into the mucosa. It is hoped that the above data might provide a physical explanation for some of the factors influencing lymph node metastasis in gastric cancers.

- 7622 GOBLET CELL-TYPE METAPLASIA OF THE GASTRIC MUCOSA IN RELATION TO SIMPLE GASTRITIS AND ULCEROUS LESIONS. (It.) Caldara, G. (12 G. da Cermenate St., Cantu, Como, Italy). Minerva Gastroent. 11(3):156-160, 1965.

Histological studies of the gastric mucosa were conducted in 20 patients subjected to gastric surgery. Goblet cell-type metaplasia was observed in the gastric mucosa of 8 of 10 patients with gastric ulcer localized in the antral region, 3 of 4 with hypertrophic gastritis, 3 of 3 with polypoid gastritis, and 1 of 3 with gastritis in association with duodenal ulcer. It is concluded that the extent and intensity of metaplasia are more marked in patients with ulcer than in those with simple gastritis. The metaplastic transformation of the epithelium is more dependent upon the type of gastric lesion and metabolic damage to the cell than upon local inflammatory reaction.

- 7623 GASTRIC LYMPHOSARCOMA. CLINICOPATHOLOGIC ANALYSIS OF 71 CASES AND ITS RELATION TO DISSEMINATED LYMPHOSARCOMA. (E.) Joseph, J. I. (Columbia U. Coll. Phys. Surg., New York, N. Y.) and R. Lattes. Am. J. Clin. Path. 45(6):653-669, 1966.

Clinicopathological studies were conducted in 71 patients (47 men and 24 women; av. age 45 yr.) with primary gastric lymphosarcoma (65) or with gastric localization of disseminated lymphosarcoma (6). Data are presented on clinical symptoms, radiological diagnosis, size and type of lesions, and microscopic findings. Treatment of patients with the primary form consisted of subtotal gastrectomy alone (21 patients) or in combination with X-rays (26); total gastrectomy alone (3) or in combination with X-rays (1); partial gastrectomy (2); biopsy alone (2) or followed by X-rays (10). Overall 5-yr. survival rate for 46 patients with the primary form was 58.7%; 10-yr. survival was 27.6%. Of patients with primary lymphosarcoma with lesions greater than 10 cm, 5- and 10-yr. survival rates were 60 and 50%, resp., following subtotal gastrectomy alone; 20 and 11.1%, resp., following gastrectomy with X-rays; 66.7 and 33.3%, resp., following biopsy and X-rays. Survival (5 yr.) was greater in patients with smaller lesions. Prognosis was best in superficial tumors confined to the mucosa and submucosa without lymphatic spread, in tumors with a

TOMACH

ollicular pattern, and in tumors with predominant lymphocytic cell type. Prognosis was about the same in tumors with intermediate and reticulum cell types. Ten patients with positive lymph nodes and tumors of more than 10 cm in size died within 2 mo. of the date of surgery; 6 showed evidence of disseminated lymphosarcoma in distant viscera and nodes. Four additional patients without lymph node involvement died within 1 yr. of diagnosis with evidence of generalized diagnosis. Four patients died postoperatively and were counted as nonsurvivors. The statistical significance of results is discussed.

- 624 GASTRIC ASPIRATION AND LAVAGE IN ACUTE POISONING. (E.) Matthew, H. (Royal Infirm., Edinburgh, Scotland), T. F. Mackintosh, S. L. Tompsett and J. C. Cameron. Brit. Med. J. 1(5499):1333-1337, 1966.

Gastric lavage was performed on 259 patients with various types of poisoning, mostly barbiturates (168 cases; 148 gastric specimens were analyzed), salicylates (25 cases; 22 specimens were analyzed), and tranquilizers. There were no cases of xerose poisoning. Gastric lavage recovered over 200 mg of barbiturate in 37% (24) of 65 patients who had taken the drug(s) up to 4 hr. previously, but recovery of 200 mg or more from patients who had been poisoned over 4 hr. previously was possible in only 1 of 65 patients. After salicylate poisoning, up to 20 g of salicylate was recovered after 9 hr. Complications of gastric lavage and aspiration were rare, even in unconscious patients. Gastric aspiration with lavage is recommended for patients poisoned with barbiturates less than 4 hr. previously, unless it can be definitely established that fewer than 10 capsules had been taken; for unconscious patients in whom the duration of poisoning is unknown; and in all cases of salicylate poisoning regardless of the time of ingestion. Such conditions probably can also apply to patients poisoned by other sedatives, tranquilizers, or antidepressants.

- 625 EFFECT OF TOTAL GASTRECTOMY ON GROWTH IN PUPPIES. (E.) Schulte, W. J. (Marquette U. Sch. Med., Milwaukee, Wis.) and E. H. Ellison. Am. J. Surg. 111(6):782-786, 1966.

Total gastrectomy, splenectomy, esophagoduodenostomy, and a single-layer anastomosis were performed at age 2 mo. in 8 puppies. The 2 animals that survived 15 mo. had both developed the habit of eating small amounts at frequent intervals. Weight loss and hypochromic anemia were markedly relieved by the admin. of an iron-extran compound (500 mg). Osteomalacia with resulting pathological fractures was treated with high doses of vitamin D. Pernicious anemia did not occur in these surviving puppies, as their diet was high in fresh liver. Other than the above-mentioned complications, the growth of these gastrectomized puppies was adequate so that these animals might serve as study models.

- 626 THE EXCRETION OF FORMIMINOGLUTAMIC ACID AND UROCANIC ACID AFTER PARTIAL GASTRECTOMY. (E.) Hoffbrand, A. V. (Postgrad. Sch. Med., London, W. 12), G. Neale, J. D. Hines and D. L. Mollin. Lancet 1(7449):1231-1236, 1966.

The excretion of formiminoglutamic acid and urocanic acid was studied in 90 patients (59 men and 31 women; age 26-83 yr.) who had undergone partial gastrectomy. Excretion was normal in 40 of the 90 patients with normal levels of folate, vitamin B₁₂, and albumin in the serum who were used as controls. Among the remaining 50 patients with folate and/or vitamin B₁₂ deficiency or hypoproteinemia, 27 had normal excretion of both metabolites, 12 had increased formiminoglutamic, but normal urocanic, acid excretion, 8 had increased urocanic acid but normal formiminoglutamic acid excretion, and 3 had increased excretion of both metabolites. The excretion of formiminoglutamic acid without urocanic acid was increased in 9 folate-deficient patients and in 3 vitamin B₁₂-deficient patients; there was no evidence of protein deficiency or liver damage in these 12 patients. Of 8 patients with increased urocanic acid without formiminoglutamic acid, 7 had hypoproteinemia; in 4, correction of hypoproteinemia was followed by normal excretion of urocanic acid. Results provide no support for the suggestion that the estimation of combined excretion is a better measure of folate deficiency than the estimation of formiminoglutamic acid excretion alone.

STOMACH

- 7627 VAGOTOMY IN BLEEDING GASTRITIS. (E.) Bartlett, M. K. (Harvard Med. Sch., Boston, Mass.) and L. W. Ottinger. Surg. Clin. N. Am. 46(3):613-618, 1966.

Vagotomy as an adjunct to gastrointestinal surgery was employed in a total of 16 cases of uncontrollable bleeding secondary to gastritis and refractory to hypothermia. There was no recurrence of bleeding in 11 who underwent distal hemigastrectomy, except for 1 patient who bled transiently during the immediate postoperative period. (Included were 2 alcoholics and 2 patients in whom habitual use of salicylates may have been a contributory factor.) There was no subsequent bleeding in 2 who underwent pyloroplasty, and bleeding following pyloroplasty was permanently stopped in a third who underwent subsequent distal hemigastrectomy and gastrojejunostomy. Bleeding episodes continued in two patients with severe aortic stenosis and a history of multiple episodes over a period of many yr., one undergoing distal hemigastrectomy and one undergoing pyloroplasty and subsequent distal hemigastrectomy. In both cases, another source of bleeding, somewhat lower in the gastrointestinal tract, appeared to be indicated by examination of the resected portion of the stomach, which failed to show either hematemesis or active bleeding from the gastric mucosa.

- 7628 MEASUREMENT OF RATE OF GASTRIC EMPTYING USING CHROMIUM-51. (E.) Griffith, G. H. (United Cardiff Hosp., England), G. M. Owen, S. Kirkman and R. Shields. Lancet 1(7449):1244-1245, 1966.

A method is reported for measuring the rate at which food leaves the human stomach (rather than merely the total time required for gastric emptying), employing an automatic scintiscanner and a breakfast into which radioactive sodium chromate has been incorporated. In preliminary studies, the fall in the external count was exponential for the greater part of the emptying process, the rate of emptying thus being expressed conveniently in terms of the intragastric half-life of the meal. Preliminary clinical findings indicated a likelihood that patients with duodenal ulcer have a faster gastric emptying rate than normal controls. The emptying rate for gastric ulcer patients was normal in approx. one-half, delayed in the remainder.

SMALL BOWEL

- 4 OSMOREGULARITY CAPACITY OF THE JEJUNUM IN SUBJECTS WITH CHRONIC ENTERITIS. (Hun.) Varró, V. (Szeged U. Med., Hungary). Magy. Belorv. Arch. 19(1):43-45, 1966.
- Anal osmotic regulation was investigated in normal subjects and in patients with enteritis. Fasting subjects received 5 ml/min. of 15% dextrose soln., slowly introduced (in 1 hr.) into the small intestine via Abbott-Miller tube, after which the jejunum was washed out 3 times with 300 ml physiologic saline soln. The glucose content of each of the 20-min. fractions obtained during the infusion period and of the saline soln. washings was determined by Somogyi's method, and the osmotic pressure, by measuring freezing point depression. Deviations of freezing-point depression values from the normal values were most conspicuous in patients in the active phase of chronic enteritis; in the inactive phase, the values tended to fall within or near the normal range. Nevertheless, the relative freedom from clinical symptoms which characterizes the inactive phase does not necessarily indicate functional integrity of the regulatory capacity of the jejunum, as the tests revealed profound disturbance of osmoregulation in some patients with a subjective sense of well-being. It is suggested that the disturbance in osmoregulation may cause mobilization of histamine, as in the dumping syndrome. The postprandial discomfort often observable in the acute phase of chronic enteritis is, in fact, similar to that in the dumping syndrome. No proof can be adduced from these studies for or against this hypothesis, however, although the level of 5-hydroxyindoleacetic acid was normal in the urine of patients with chronic enteritis, the determinations were not made at the time when the malaise was being experienced.
- 5 CHANGES IN THE ACTIVITY OF CHOLINOMIMETIC SUBSTANCES IN THE INTESTINAL WALL IN EXPERIMENTAL INTESTINAL OBSTRUCTION. (Rus.) Dederer, Iu. M. (Altai Med. Inst., Barnaul, USSR). Pat. Fiziol. Eksp. Ter. 10(1):69-71, 1966.
- After experimental induction of intestinal strangulation in guinea pigs, extracts from the wall of adducent, strangulated, and abducent intestinal loops were tested for their content in cholinomimetic substances in the isolated frog heart. Perfusion with extracts from loops leading to and from the strangulated loop produced a decrease in the amplitude and frequency of the contractions, whereas extracts from the strangulated loop produced an increase. This indicates that accumulation of cholinomimetic substances had occurred in the walls of both the adducent and abducent loops, and especially in the latter. In the portion of the intestinal wall where the blood supply was interrupted, substances with a weak epinephrine-like effect were demonstrated, along with the decreased activity of cholinomimetic substances.
- 6 THE PHYSIOPATHOLOGICAL IMPORTANCE OF ENDOTOXIN IN ILEUS. (Ger.) Blümel, G. (U. Vienna, Austria) and R. Gottlob. Klin. Med. (Wien) 21(4):176-177, 1966.
- Three days after ileus was induced in rats by ligation of an aboral ileal loop, the presence of endotoxin in the mesenteric venous blood was demonstrable via a localized sensitization of the Schwartzmann-Sanarelli reaction in rabbits. This was created by intracutaneous inj. of the test substance 24 hr. before i.v. inj. of coli-endotoxin, which then induced hemorrhaging at the site of the original (sensitizing) inj. When the rabbits employed also showed endotoxin in the posthepatic blood flow due to artificial ileus, the increased resorption of endotoxin had the same effect as a sensitizing dose would have had, but the anaphylactic reaction was systemic and fatal within a few hours. Both ileus-bearing rabbits and intact rabbits in prolonged, endotoxin-induced shock were hypersensitized to withdrawal of blood. The doses of 10-15 ml in ileus-bearing or 60-80 ml in intact animals triggered a syndrome in which uncontrollable screaming continued even under narcosis until the animals died. This syndrome was shown to result from the presence of free plasmakinins.
- 7 ENZYME ACTIVITY OF THE SMALL INTESTINE IN CHRONIC, NON-SPECIFIC ENTEROPATHIES. (Ger.) Fodor, O. (U. Cluj, Rumania), D. Dumitrascu, G. Ciofu,

SMALL BOWEL

I. Iltu, S. Tragor, A. Nicoara, C. Calu and D. Grigoras. *Zschr. Gastroent.* 4(1):26-32, 1966.

As compared to normal controls, median values for enterokinase and alkaline phosphatase content of jejunal secretions were significantly increased in patients with chronic, non-specific enteropathy, while alkaline phosphatase content was also significantly increased in biopsy specimens of jejunal mucosa. There was no demonstrable relationship between enzyme activity and intestinal pH, length of illness, or age of patients. In achlorhydric patients and those who had undergone gastric resection (with or without impairment of intestinal function), mean values for enterokinase activity in the small intestine were increased significantly (especially in the absence of diarrhea), and it is concluded that a compensatory mechanism was involved, with enzyme hypersecretion accompanying exudation of endogenous proteins into the intestinal lumen and consequent enzyme insufficiency in the tissues of the upper intestinal tract. It is suggested that a similar mechanism may be involved in non-specific enteropathy, with enzyme hypersecretion in the small intestine, accelerated absorption of trypsin and increased intracellular alkaline phosphatase activity paralleling demonstrable pancreatic hyperfunction.

7698

A METHOD OF DEMONSTRATING INTESTINAL VIABILITY. (E.) Dineen, P. (Corney U. Coll. Med., New York, N. Y.), D. Goulian, Jr. and C. K. McSherry. *Am. J. Gastroent.* 45(5):335-341, 1966.

Necrosis of segments of the ileum was produced in rabbits and dogs by ligation and division of the branches of the mesenteric artery supplying these areas, as well as the collateral marginal vessels. Bromphenol blue (15% soln.; 0.15 mg/g body wt.) was admin. i.v. within 5 min. after ligation of the blood supply. Intact segments of the intestinal mucosa excreted the dye into the lumen, whereas the dye was secondarily diffused into the nonviable segments; these changes were noted within 10 seconds of admin. of the dye. All animals survived the procedure and showed no toxic reactions to the dye; all died of intestinal gangrene 1-3 days later. Autopsy examination of animals surviving 18-24 hr. demonstrated complete clearing of the dye from all viable tissues and retention by the zones of necrosis. Toxicity studies were carried out in mice. After admin. of 0.1-10 ml of 0.1-17% bromphenol blue, the dye was taken up by the kidneys, bladder, liver, intestine, and gallbladder immediately after inj., but after 24 hr. the only traces found were in the distal colon. Chronic toxicity studies in mice demonstrated no toxic reactions after inj. of 0.5 ml of 10% bromphenol blue soln. every 7 days for 6 mo.

7699

CHRONIC INTESTINAL ISCHAEMIA. (E.) Guldhammer, E. H. (Fredriksborg Royal Cent. Hosp., Hillerod, Denmark), F. Lund, T. Poulsen and H. Schiødt. *Acta Chir. Scand.* 131(4):366-373, 1966.

Two patients with chronic occlusion of the superior mesenteric artery (a 66-year-old man with classical signs and symptoms and a 41-year-old woman who presented with pain not distinctly related to meals and occlusion of only 1 of the 3 main arteries at aortography) were treated by endarterectomy and patch-grafting and showed promising clinical results. The possibility of occlusive arterial disease should always be kept in mind in patients with chronic abdominal pain. Aortography with 2-plane projections, possibly supplemented by selective arteriography of individual visceral branches, is the usual diagnostic method. Indications for surgery are discussed.

7700

STUDIES ON INTRAPERITONEAL ADHESIONS. I. EXPERIMENTAL STUDIES ON INTESTINAL ADHESIONS AND CHANGES IN ACTION POTENTIALS OF THE INTESTINE. (Jap.) Tsugu, Y. (Toho U. Sch. Med., Japan). *Nippon Geka Hokkan (Arch. Jap. Chir.)* 35(1):107-121, 1966.

Adhesions were induced in the terminal ileum of 122 dogs by mechanical (crushing with moist gauze) or chemical (2% tincture of iodine) means. Macroscopic findings included the formation of an i.p. exudate and edema of the intestinal wall by 15 min. after surgery, the beginning of adhesion between the intestinal walls by 3-6 hr., and the formation of fibrinous adhesions by 24 hr. Microscopic examination revealed the presence of a fibrinous substance in the exudate and cellular infiltration of the serosa and subserosa within 1 hr. after surgery; by 3-6 hr., these

ALL BOWEL

anges became more marked and periodic acid-Schiff-positive cells were observed; 1 wk., all organization of adhesions was complete. Electromyographical studies showed a gradual decrease in the action potential of the adhesion/ileum in relation to the growth of the adhesion. This effect was more marked with regard to spike-potential and discharging frequency. Return to normal occurred by 1 wk. Data suggest a correlation between the decrease in action potential and pathological changes in the intestinal wall.

01 DISEASES OF RHESUS MONKEY. II. SMALL INTESTINE. (E.) Guleria, S. S. (Inst. Postgrad. Med. Ed. Res., Chandigarh, India), R. N. Chakravarty, L. S. Chawla and P. N. Chhuttani. J. Assn. Physicians India 14(4):239-242, 1966.

The small intestines of 142 wild rhesus monkeys were examined within 1 wk. of capture of the animals. Helminthic infestations were seen in 16 animals (Physaloptera 7, Necator americanus in 3, Cesphagostomum in 4, Bertiella in 2, Strongyloides in 1, double infestation in 1) and protozoan infestations in 8 animals (Trichomonas 5, Giardia lamblia in 3), for a total incidence of 17%. Inflammation, acute or chronic, was seen in 48 animals (34%). Intussusception was seen in 16 animals (11.3%), all of which were very young. The fecal fat content was 1-4 g%, and there was no significant difference between the fecal fat content of monkeys with and without small intestinal diseases. There were no cases of malabsorption, tuberculosis, congenital anomalies, or neoplastic disease.

02 CHANGES IN BLOOD SEROTONIN CONCENTRATION AND URINARY 5-HYDROXYINDOLEACETIC ACID EXCRETION IN MECHANICAL OBSTRUCTION OF THE SMALL INTESTINE. I. EXPERIMENTAL INTESTINAL OBSTRUCTION IN THE DOG. (E.) Warner, R. R. P. (Mt. Sinai Hosp., New York, N. Y.), M. G. Feldman, G. M. Warner and I. H. Parnes. Surgery 59(5):750-757, 1966.

Blood serum serotonin conc. and urinary 5-hydroxyindoleacetic acid excretion were investigated in 15 female mongrel dogs before and during mechanical obstruction produced by encasement of an exteriorized loop of terminal ileum within a tube (cicle of skin) and after release of the obstruction. Fairly prompt and continued increases in serum serotonin conc. and urinary 5-hydroxyindoleacetic acid excretion were observed while the intestine was obstructed, with rapid return to normal levels on release of the obstruction. Similar measurements in 7 dogs before and during adynamic ileus secondary to experimentally-induced bile peritonitis showed no change in serum serotonin conc. and 5-hydroxyindoleacetic acid excretion. The metabolic activity of excessively proliferating intestinal bacteria seems to be the most important factor in bringing about increases in these indoles in mechanical obstruction of the terminal ileum. (See also 7703.)

03 CHANGES IN BLOOD SEROTONIN CONCENTRATION IN MECHANICAL OBSTRUCTION OF THE SMALL INTESTINE. II. FINDINGS IN PATIENTS WITH INTESTINAL OBSTRUCTION. (E.) Warner, R. R. P. (Mount Sinai Hosp., New York, N. Y.), M. G. Feldman, G. M. Warner and I. H. Parnes. Surgery 59(5):758-764, 1966.

Blood serum serotonin was determined in 28 patients with untreated obstruction of the small intestine or colon. The site of obstruction was in the midjejunum or more distal in 24 patients; elevated serum serotonin levels were observed in 22 of these patients during obstruction with return to normal after surgical decompression. The site of obstruction was in the most proximal portion of the small intestine in the other 4 patients; serum serotonin was normal during obstruction and did not change after surgical decompression. Normal serum serotonin was found in 7 patients with intestinal obstruction which, prior to surgery, was treated with long tube decompression or antibiotics, or did not manifest small intestinal dilatation. Normal serum serotonin was also found in each of 29 patients with adynamic ileus of varying etiology. Twenty-four-hr. urinary excretion of 5-hydroxyindoleacetic acid was measured during obstruction and postoperative decompression in 2 patients with distal small intestinal obstruction; excretion was abnormally elevated during obstruction and returned to normal following decompression. It is concluded that blood serum serotonin conc. is abnormally increased during untreated mechanical obstruction of the intestine when the site of the obstruction is more distal than the most proximal part of

SMALL BOWEL

the small intestine and the obstruction is accompanied by small intestinal dilatation. The excessive outgrowth of bacterial flora in the area is possibly the major cause of the increase. It is suggested that measurements of serum serotonin and urinary 5-hydroxyindoleacetic acid may be clinically useful in differentiating mechanical intestinal obstruction from adynamic ileus. (See also 7702.)

- 7704 HIGH SERUM-FOLATE LEVELS IN INTESTINAL BLIND-LOOP SYNDROME. (E.) Hoffbrand, A. V. (Postgrad. Sch. Med., London, W. 12), S. Tabaqchali and D. L. Mollin. Lancet 1(7451):1339-1342, 1966.

High serum folate activity (using Lactobacillus casei as test organism) was found in 4 patients (2 men and 2 women; age 39-82 yr.) with intestinal blind loop syndrome due to jejunal diverticulosis (1), jejunal diverticulosis and Polya partial gastrectomy (1), Polya partial gastrectomy (1), or multiple blind loops resulting from entero-entero anastomoses for tuberculous peritonitis. Each patient had megaloblastic anemia due to vitamin B₁₂-deficiency and steatorrhea but normal glucose and xylose absorption. These high levels were not caused by accumulation of 5-methyl tetrahydrofolate acid due to vitamin B₁₂-deficiency since the high levels did not return to normal when the deficiency was corrected. The most likely explanation seems to be the absorption of folate material synthesized by bacteria in the small intestine.

- 7705 ANTIPERISTALTIC BOWEL SEGMENT IN THE TREATMENT OF THE SHORT BOWEL SYNDROME. (E.) Shepard, D. (1211 W. Peachtree St., Atlanta, Ga.). Ann. Surg. 163(6):850-855, 1966.

A review of the effects of antiperistaltic reversal of a short segment of bowel in dogs with massive small bowel resections is followed by report of a patient whose small intestine was less than half normal length, due to previous excision of a considerable part of the ileum which had become adherent following appendectomy. Symptoms included intractable, frequent diarrhea, borborygmi, flatulence and acute abdominal pain requiring opiates. Antiperistaltic reversal of a 5-inch segment of jejunum, 36 inches distal to the ligament of Treitz, with double jejunojejunostomy resulted in normalization of gastrointestinal transit time, cessation of diarrhea and total disappearance of pain. Thirteen mo. later, the patient's work-load and activities were entirely normalized, without special dietary requirements.

- 7706 EFFECT OF GASTROINTESTINAL SECRETIONS ON THE FORMATION OF HEMORRHAGIC INTESTINAL NECROSIS IN Escherichia coli ENDOTOXIN SHOCK. (E.) Evans, W. E. (Marquette U. Sch. Med., Milwaukee, Wis.), R. T. Shore, L. C. Carey and J. C. Darin. Am. J. Surg. 111(6):799-804, 1966.

Performance of total gastrectomy or antrectomy with vagotomy prior to the admin. of Escherichia coli endotoxin (1.5 mg/kg i.v.) prevented the subsequent formation of hemorrhagic intestinal necrosis in dogs, but the mortality rate remained 100% as in the controls. The hemorrhagic lesions were slightly milder in dogs which underwent ligation of the pancreatic duct. Exclusion of the small intestine or cholecystojejunostomy did not influence the development of intestinal hemorrhagic necrosis.

- 7707 EFFECT OF INTRAPERITONEAL HYALURONIDASE ON THE REFORMATION OF INTESTINAL ADHESIONS. (E.) Stoehr, B. J. (Marquette U. Sch. Med., Milwaukee, Wis.), J. E. Gutierrez and A. A. Close. Am. J. Surg. 111(6):881-883, 1966.

Hyaluronidase did not significantly decrease the extent of the reformation of intestinal adhesions produced by surgical trauma in dogs. The following treatment was admin. i.p. prior to abdominal closure in 47 dogs known to have adhesions (brought about by serosal abrasion) which involved at least a third of the intestinal length: 30 ml saline (controls); saline with hyaluronidase on the day of operation (1500 U); saline with hyaluronidase as above, then 750 U/day for 4 days (i.p.); saline with larger doses of hyaluronidase (1500 U/day for 4 days); and saline with 1 large dose of hyaluronidase (7500 U). Hyaluronidase was nontoxic at all doses. Penicillin and dihydrostreptomycin were also admin. postoperatively for 3 days.

- 7708 ACUTE ENTERITIS DUE TO Salmonella typhimurium IN OPIUM-TREATED GUINEA PIGS. (E.) Kent, T. H. (Walter Reed Army Inst. Res., Washington, D. C.)

- S. B. Formal and E. H. Labrec. Arch. Path. (Chicago) 81(6):501-508, 1966.
- guinea pigs with intestinal motility altered by admin. of opium tincture (1 ml p.o.), the disease produced by Salmonella typhimurium (p.o.; 10^8) developed into severe diffuse ileitis and moderate jejunitis, which was fatal in 3 days. The disease produced in normal guinea pigs from this dosage of bacteria took the form of typhoid-like granulomatous lesions and caused death in 4-10 days. Fluorescent titerum technics demonstrated S. typhimurium invasion in the intestinal epithelium and lamina propria in the opium-treated animals. Large numbers of salmonellae were cultured from the ileum of these animals, while the controls were able to rapidly clear the organism from the small intestine. When small doses of S. typhimurium were given to opium-treated guinea pigs, a more chronic typhoid-like illness was produced.

Peptic Ulcer

- 7753 DEMUCOSATION AND OBLITERATION OF THE LESSER CURVATURE OF THE STOMACH. (Bul.) Todorov, T. (Higher Med. Inst., Varna, Bulgaria). Khirurgia (Sofia) 18(6):650-655, 1965.

A method of surgical treatment of gastric ulcer called by the author demucosation and obliteration of the lesser curvature of stomach is described. By means of gastrotomy the lesser curvature is reached from within. The mucous membrane is exfoliated and elliptically excised under procaine anesthesia. The underlying layers of the anterior and posterior gastric walls are sewed (obliteration) one to other, followed by a continuous suture of the resected mucosa edges. The gastrotomy is closed on two levels. The operation was originally tried on 4 dogs and afterwards on 5 patients. In one patient the operation was combined with pyloroplasty and in another, due to a duodenal localization, by an ulcer excision. The operation was easily tolerated by the patients. Two of them were under observation for 6 mo. The physiologic advantages as well as the weak points of the method are pointed out. This method is still under investigation.

- 7754 GASTRIC ACIDITY: ALKALIES AND ANTICHOLINERGICS. (Dut.) Lips, J. B. (Groot Hosp., 'S-Hertogenbosch, The Netherlands). T. Gastroent. 9(1): 77-89, 1966.

In patients hospitalized for conservative treatment of active duodenal ulcer, a combination of calcium carbonate and magnesium oxide (2.0 and 0.4 g/dose, resp.) showed superior antacid effects to those of the same combination in doses of 1.0 and 0.2 g/dose, resp., to aluminum hydroxide (0.5 g/dose), to aluminum hydroxide and magnesium trisilicate (0.5 and 1.0 g/dose, resp.) and to standard i.m. doses of atropine. When the preferred combination was admin. every 2 hr., supplementing milk or a small meal, pH (as determined by gastric sound) was maintained above 4.0 in 93% of the patients after 15 min., in 69% after 1 hr., in 50% after 1 1/2 hr. and in 33% after 2 hr. Doubling the dose did not prolong the effect significantly, but hourly admin. gave satisfactory results in 50% of the patients not responding satisfactorily to the 2-hr. schedule. A total dose of magnesium oxide exceeding 3 g/day will induce diarrhea. In a few cases the effect appeared to be somewhat potentiated by propanthine (40-45 mg/dose, 4 times a day), or by scopolamine methyl nitrate (Skopyl) (1.3-3.0 mg/dose, 4 times a day); although neither provided a satisfactory substitute, even when propanthine was admin. in doses as high as 120 mg/dose, 4 times a day. Sodium bicarbonate (45-90 g/day in 3 liters of milk; by continuous drip) also proved satisfactory, although it was tolerated well for several wk. In 4 of 6 patients with whom it was tried, supplementing the preferred combination with poldine methosulfate (Nacton; 8-12 mg/dose, 4 times a day) appeared to decrease nocturnal gastric secretions.

- 7755 FAECAL FAT EXCRETION AND STOOL COLOUR AFTER VAGOTOMY AND PYLOROPLASTY. (E.) Wastell, C. (Westminster Sch. Med., London) and H. Ellis. Brit. Med. J. 1(5497):1194-1197, 1966.

Fecal fat and urobilinogen excretion and bowel frequency were studied in 14 patients subjected to total vagotomy and pyloroplasty (Group 1) and 6 patients subjected to anterior selective vagotomy and pyloroplasty (Group 2). Mean fecal fat excretion (g/24 hr.) increased from 2.4 to 4.6 at 1 wk. after surgery in 11 patients and to 6.7 g/24 hr. more than 6 wk. after surgery in 13 patients of Group 1; an increase from 2.4 to 4.3 after 1 wk. was observed in 4 patients and to 6.4 g/24 hr. after more than 6 wk. was observed in all patients of Group 2. Mean fecal urobilinogen conc. more than 6 wk. after surgery was decreased from 83.1 to 48.1 mg/100 g stool in 13 patients of Group 1 and from 79.6 to 52.0 mg/100 g in 5 patients of Group 2. Based on calculations of stool wt. increase, daily urobilinogen excretion (mg/24 hr.) at more than 6 wk. fell from 61 to 57 in Group 1 and from 72 to 54 in Group 2. Mean frequency of bowel action 6 wk. or more after surgery rose from 0.9/day to 1.6/day in 13 patients subjected to total vagotomy and pyloroplasty and from 0.9/day to 1.9/day in 9 patients subjected to anterior selective vagotomy and pyloroplasty. No significant quantitative differences were observed between patients of both groups.

- 56 ULCERATION OF INTERPOSED ILEAL SEGMENTS AFTER VARIOUS DEGREES OF VAGOTOMY. (E.) Hilbun, B. M. (U. Mississippi Med. Ctr., Jackson), W. O. Barnett and J. T. Davis, Jr. Surg. Gynec. Obstet. 122(6):1251-1254, 1966.

The effect of selective vagotomy was studied on experimental peptic ulcer produced in dogs by placing a 20-cm segment of ileum between the stomach and duodenum in an end-to-end anastomosis. There were 20 dogs in each group studied. When the anastomosis was done without disturbing the vagus, 18 of 20 dogs developed ulcers in the ileal segment; anterior vagotomy alone did not significantly reduce the ulcer incidence (17 of 20) but posterior vagotomy alone (10 of 20), total vagotomy (6 of 20) and selective division of the anterior and posterior gastric vagus nerves (4 of 20) did produce significant protection. Antrectomy without vagotomy produced an incidence of 16 of 20 dogs with ulcers, while anterior vagotomy with antrectomy (both effective alone) significantly reduced the ulcer incidence to 4 of 20. The data suggest that selective vagotomy can be as effective as total vagotomy in the prevention of peptic ulcer.

- 57 RECURRENT ULCERATION AFTER OPERATION FOR PEPTIC ULCER: RESULTS AFTER GASTROENTEROSTOMY, GASTRECTOMY AND VAGOTOMY IN 64 CASES. (E.) Thompson, J. E. (Roosevelt Hosp., New York, N. Y.) and T. H. Dailey. Ann. Surg. 163(5):704-712, 1966.

From 1955-64, recurrence of ulceration was observed in 64 patients subjected to gastric surgery, including 19 following gastroenterostomy, 43 following gastrectomy, 1 following pyloroplasty, and 1 following pyloroplasty and vagotomy. In a series previously reported by the same author (1937-54), recurrent ulceration was observed in 63 patients (35 gastroenterostomy and 28 gastrectomy). Of a total of 19 patients from the 1955-64 series who developed recurrent ulceration, after gastroenterostomy 10 were treated subsequently by gastrectomy, among whom 1 died during surgery, 1 developed a second recurrent ulcer, 4 showed good response for 1-5 yr., 5 for 5-10 yr., and 2 were lost to follow-up; 3 were treated by gastrectomy and vagotomy, all of whom showed good response for 1-5 yr.; 2 were treated by trans-abdominal vagotomy, of whom 1 showed good response for 1-5 yr. and 1 was lost to follow-up; 1 was treated by ablation gastroenterostomy and developed a second recurrent ulcer. Among 13 patients who developed recurrent ulceration following gastrectomy, 13 were subsequently treated by revision gastrectomy with vagotomy, of whom 1 died during surgery, 1 developed a second recurrent ulcer, 9 showed good response for 1-5 yr., 1 for 5-10 yr., and 1 was lost to follow-up; 11 were treated by trans-abdominal vagotomy, among whom 1 died during surgery, 5 showed good response for 1-5 yr., 1 for 5-10 yr., and 4 were lost to follow-up; 7 were treated by trans-thoracic vagotomy, of whom 1 developed a second recurrent ulcer, 4 showed good response for 5-10 yr., and 2 were lost to follow-up; 2 were treated by revision gastrectomy, of whom 1 showed good response for 1-5 yr. and 1 was lost to follow-up; 5 were treated by conversion of Billroth II to Billroth I, of whom 1 developed a second recurrent ulcer, 1 showed good response for 1-5 yr., 2 for 5-10 yr., and 1 was lost to follow-up; 5 were treated by miscellaneous procedures, of whom 1 died during surgery, 2 showed good response for 5-10 yr., and 2 were lost to follow-up. Ulcer recurrence rate for patients with marginal ulcers was 3-4 times greater than for patients with duodenal ulcer undergoing initial gastrectomy.

- 58 PSYCHOSOMATIC STUDIES IN DUODENAL ULCER. (Ger.) Lang, N. (U. Marburg, Germany), U. Hoffmann and L. Breitenstein. Verh. Deutsch. Ges. Inn. Med. 71:397-404, 1965.

A series of questionnaires and semi-projective tests was administered to 63 ulcer patients, 20 patients with chronic gastritis and a control group of 40 persons, composed of "normal" subjects and juvenile hypertensives. Included were a personality questionnaire developed by the Psychological Institute of the University of Marburg, the Audley Test (of neurotic tendencies), the Wartegg Drawing-Completion Test, the Saw-a-Tree Test, Rosenzweig's Picture Frustration Test and Meili's Cross-Out Test. Results indicated that there was no one "ulcer type," but that several characteristics which might interfere with social adaptation were indicated more frequently in one or another group of ulcer patients than they were by controls. Among these

were feelings of frustrated ambition, increased emotional lability and decreased psychomotor aggressiveness. Fully-developed neuroses were rare; more frequently seen were such neurotic tendencies as over-concern about successful performance (either via compulsive perfectionism or via over-zealousness without insight) or inability to resolve problems by the use of relatively simple, obviously adequate procedures. The authors feel that prophylaxis, as concerns the recurrence of an ulcer, could be enhanced significantly by applying these or similar procedures in individual cases and using results to facilitate the patient's adjustment by eliminating potentially frustrating situations from his environment or helping him to deal with them successfully through psychotherapy.

- 7759 HISTOLOGIC AND CLINICAL FINDINGS BEARING ON THE ETIOLOGY OF GASTRODUODENAL ULCERS. (Ger.) Hoffmann, V. (48 von Groote St., Cologne, Germany). Zbl. Chir. 91(13):452-456, 1966.

Histologic study of specimens derived at the time of surgery for gastroduodenal ulcer showed characteristic changes in both Brunner's glands and muscular tissue immediately underlying apparently intact mucosal villae near a clearly-established, deep ulceration. These changes resembled those seen in scarification, but occurred in intact, rather than regenerative, tissue. They did not penetrate to the outer surface, and appeared to result directly from a localized disturbance of peripheral circulation. Further study of ulcers in various stages of development appeared to confirm that the ulcerative process began within the wall of the area involved and then developed outward, rather than beginning with erosion of the outer surface. Two long-term follow-up studies of ulcer patients undergoing minimal gastric resection (with a precolonic, terminolateral anastomosis involving a short jejunal loop, instead of an enteroanastomosis) showed that recurrence of ulceration was seen no more frequently than in patients undergoing resection of 2/3 - 3/4 of the stomach. The author concludes that massive gastric resection is not justified in the treatment of gastroduodenal ulcer and that such ulcers actually result from localized disturbances of the peripheral circulation, which may be either functional or organic in origin.

- 7760 FUNCTIONAL AND METABOLIC EFFECTS OF TOTAL AND SELECTIVE VAGOTOMY. (E.) Williams, E. J. (St. Mary's Hosp. Sch. Med., London, W. 2) and W. T. Irvine. Lancet 1(7446):1053-1057, 1966.

Investigation of fat and lactose metabolism and gallbladder function was carried out in 65 patients before and after total (43 cases) or selective (22 cases) vagotomy combined with pyloroplasty or gastroenterostomy. Four patients with total but none with selective vagotomy had diarrhea. Incomplete vagotomy occurred in 5% of the total and 7% of the selective vagotomy groups. Elevated fecal fat values occurred equally between the two groups and 16.2% of the total and 13.6% of the selective vagotomy patients lost over 7 g/day of fecal fat. Optical plasma density following a fat meal was compared in 19 total and 9 selective vagotomy patients to 20 control subjects to study fat absorption. There was a significant decrease in fat absorption from control values following vagotomy but there was no difference between the vagotomized groups. A flat lactose tolerance curve was found in a small number of patients from both vagotomized groups. No difference from preoperative values was found in the fasting gallbladder vol. in either of the vagotomized groups. It was concluded that selective vagotomy had no advantage over total vagotomy for changes in fat metabolism or gallbladder function.

- 7761 DISABILITIES WHICH MAY FOLLOW THE PEPTIC ULCER OPERATION. (E.) Tanner, N. C. (Charing Cross Hosp., London). Proc. Roy. Soc. Med. 59(4):362-368, 1966.

Effects of a type of operation (the aim of which is essentially to reduce normal digestive activity) are discussed in this review. Recurrent gastroduodenal ulcer may occur after any form of ulcer operation except total gastrectomy. As to non-ulcer symptoms after operation for ulcer, digestive deficiencies are noted by a minority after partial gastrectomy (milk, eggs, sometimes fried foods or vegetables). This food intolerance is most marked after Polya-type operations. After gastrectomy

There may be deficient absorption of iron and calcium. This may be due to overly rapid passage through the stomach and perhaps bypassing the duodenum. Among early post-cibal symptoms, the commonest, a feeling of "fullness" after eating, occurs in 50% after vagotomy and after gastrectomy. Among other disabilities which may occur are regurgitation and vomiting of gastric or bilious material, hypoglycemic-like attacks, disturbances of bowel action, vagotomy cramps, and cardiospasm. The medical, prophylactic, and surgical management of these conditions is also discussed.

- 62 EVALUATING AND PHOTOGRAPHING EXPERIMENTALLY INDUCED STOMACH ULCERS. (E.) Mikhail, A. A. (Maudsley Hosp., London, S. E. 5) and H. C. Holland. J. Psychosom. Res. 9(4):349-353, 1966.

Based on experience of about 500 rat stomach examinations, the authors describe a method for evaluating the extent of ulceration in rat stomachs more accurately. The steps include application of a Plaster-of-Paris corselet held in place by rubber bands, inflation of the stomach, examination by transillumination, photography of the ulcerated area, and preservation of the stomach for subsequent examination. Using this technic, the severity as well as the incidence of stomach ulceration can be assessed. Various methods for evaluating the degree of severity of ulceration and the advantages of using photography are discussed.

- 63 EARLY HISTORY VARIABLES IN PREDICTING SURGICAL SUCCESS FOR INTRACTABLE DUODENAL ULCER PATIENTS. (E.) Pascal, G. R. (VA Hosp., Atlanta, Ga.), J. C. Thoroughman, J. R. Jarvis and W. O. Jenkins. Psychosom. Med. 28(3):207-216, 1966.

In duodenal ulcer patients (all male veterans) coming to surgery for intractability and considered surgical failures 2 yr. after surgery were matched by aged, education, and vocation with 10 similar patients considered to represent surgical successes. Each was interviewed at the time of surgery about the behavior of their parents toward them during the first decade of life. The reports of parental behavior were then rated on 10 variables, including frequency of contact, activities, displays of affection, restraints, physical punishment, religious behavior, physical health, compatibility of spouse, role, and providing behavior. Although there was no significant relationship between all variables combined and surgical outcome, only 1 variable, Displays of Affection from mother, reached the desired level of significance in both experiments. This finding was not considered specific to duodenal ulcer or surgical intractability in duodenal ulcer. When the variables were applied to a prior series of patients falling in the middle group of the Deprivation scale, the prediction was correct 11 times for the sample of 12 cases.

- 64 PEPTIC ULCER DISEASE. MORBIDITY AND MORTALITY IN PATIENTS UNDERGOING OPERATION. (E.) Fisher, R. D. (Johns Hopkins U. Sch. Med., Baltimore, Md.), P. A. Ebert and G. D. Zuidema. Arch. Surg. (Chicago) 92(6):909-916, 1966.

The overall mortality rate in 700 patients operated for benign gastric or duodenal ulcer in 1952-1965 was 6% (43 patients). After elective surgery (for pain, obstruction, or chronic bleeding) the mortality rate was 2.5% (9 of 359 cases); after emergency procedures for perforation it was 4.4% (8 of 180 cases); after emergency surgery for hemorrhage, the mortality rate was 21.6% (24 of 111 cases). In a later group of 50 patients presenting with massive hemorrhage, treatment with transfusions to correct the hypotension, before induction of anesthesia, reduced the mortality rate to 4% (2 cases). The major causes of death were cardiovascular and pulmonary complications, apparently related to periods of hypotension which resulted in myocardial infarction, renal ischemia progressing to oliguria, and aspiration pneumonia. Such complications were rare or absent in patients undergoing emergency surgery for perforated ulcers, however, indicating that emergency surgery alone is not associated with a significant increase in operative morbidity or mortality.

- 65 TECHNICAL COMPLICATIONS OF TRANSABDOMINAL VAGOTOMY. (E.) Simmons, R. L. (Columbia U. Coll. Phys. Surg., New York, N. Y.), R. Back, H. D. Harvey and F. P. Herter. Arch. Surg. (Chicago) 92(6):922-927, 1966.

Bilateral subdiaphragmatic vagotomy was performed or attempted on 883 ulcer patients between 1951-1964, usually in combination with gastric resection. Technical complications were encountered in 42 cases (4.7%), the most frequent being hemorrhage (splenic in 20, operative in 10, postoperative in 3). Only 1 death was attributable to a technical error; this patient and 6 others (0.8% of the group) showed prolonged morbidity or required further surgery. Two cases (1 fatal) of postoperative mediastinal hemorrhage after subdiaphragmatic vagotomy are described; in the patient who died, autopsy demonstrated retraction of bleeding vessels into the mediastinum. It is concluded that operative hemorrhage, splenic laceration, and esophageal perforation, if recognized at operation, can be corrected without undue difficulty. In this series of patients, vagotomy combined with distal gastric resection reduced the incidence of recurrent ulceration from 8.0% (with subtotal gastrectomy alone) to 2.0%. Criteria used to determine incomplete vagotomy (72 patients) are also discussed.

- 7766 TRANSAMINASE DEFICIENCY IN ALCOHOLICS AND CASES OF PEPTIC ULCER. (E.) Rutter, L. (290 West End Lane, Hampstead, N. W. 6, England). Nature (London) 210(5035):538, 1966.

In 15 alcoholics under vitamin treatment, the internal rate of conversion of vasodilating nicotinic acid to non-vasodilating nicotinamide was greatly retarded, as shown by the high incidence of flushing with low doses of nicotinic acid (50-75 mg). A similar vasodilating response was also seen in 5 non-alcoholic patients with ulcers. The dose of nicotinic acid required to produce similar flushing in 6 patients without histories of alcoholism or chronic gastric abnormalities was 150-200 mg; however, this vasodilating dosage was reduced if nicotinic acid was admin. after a meal. It is suggested that the same enzymes are implicated in the metabolism of food and of nicotinic acid; competition for a transaminase (e.g., pyridoxal-5-phosphate) is considered probable.

- 7767 INFLUENCE OF FEMALE SEX HORMONES ON ULCERS OF THE UPPER GASTROINTESTINAL TRACT. (Ger.) Kronberger, L. (U. Graz, Austria) and H. Hafner. Endokrinologie 49(5/6):185-198, 1966.

The male:female ratio in 2064 patients operated for gastric or duodenal ulcers was 4:1 (1671:393). The ulcer incidence has increased in recent yr. in patients under 20 (14 male, 5 female) and at ages 21-40 (564 male, 73 female). The peak incidence of duodenal and gastric ulcer was at ages 41-60 in both sexes; in men, the curve increased very rapidly between ages 11-40, leveled off at ages 41-60, then dropped sharply. In women, there was also a plateau at ages 41-60 followed by a sharp decrease, but the increase in ulcer incidence at earlier ages was much slower. In aged patients, the incidence of new ulcers and of perforation was high. The effect of sex hormone treatment on the incidence of histamine-induced ulcers was studied in guinea pigs. After treatment with histamine (1 mg/day for 10 days s.c., ending 1 day before sacrifice), the gastric ulcer incidence in male and female animals was 90.9% and 36.1%, resp. In oophorectomized males and oophorectomized females, the ulcer incidence was 80% in both cases. After admin. of estriol succinate (5 mg/day for 10 days i.m.) together with histamine, the ulcer incidence was 30% in males and 0% in females. In intact male guinea pigs treated with histamine together with either hexestrol diphosphate (25 mg/day i.m.) or estriol succinate (10 mg/day p.o.), there were no ulcers. In all treated groups, however, the intragastric pH was reduced from the normal 5.5-6.0 to 1-2. Gastritis did not develop in any of the animals that failed to develop ulcers.

- 7768 PREVENTION OF ULCER FORMATION BY HYPOPHYSECTOMY. (E.) Robert, A. (Upjohn Co., Kalamazoo, Mich.), J. P. Phillips and J. E. Nezamis. Proc. Soc. Exp. Biol. Med. 121(4):992-995, 1966.

Female Sprague-Dawley rats, which were hypophysectomized prior to 4 days of treatment with prednisolone (5 mg/day s.c.), demonstrated a resistance to the formation of steroid-induced gastric ulcers. The longer the interval between the operation and treatment, the greater was the resistance. An interval of 17 wk. gave 98% resistance, yet other effects of the drug, such as body wt. loss and spleen atrophy were about the same in all rats regardless of the time of hypophysectomy. A non-pituitary-dependant humoral factor, effective peripheral secretion from some

ALL BOWEL

gastrointestinal gland, and the corpora lutea, are all discussed as possible explanations for this progressive resistance.

- 69 EFFECTS OF VAGOTOMY AND PYLOROPLASTY ON STEROID-INDUCED GASTRIC ULCERS IN RATS. (E.) Kelley, J. L. (St. Joseph Mercy Hosp., Ann Arbor, Mich.) and W. J. Regan. Am. J. Surg. 111(5):664-667, 1966.
In both pyloroplasty (Heineke-Mikulicz type) and bilateral vagotomy, performed in adult female white rats prior to the admin. of dexamethasone (0.15 mg/100 g/day for 4 days s.c.), gastric ulcers occurred in only 7 of 20 rats. None of the rats in this group had free stomach acid. In contrast, all 20 rats without a prophylactic operation had gastric ulcers and 50% showed free stomach acid. Pyloroplasty alone resulted in ulceration in 3 cases; 3 animals in this group also had free stomach acid. In another series, when both procedures were performed following 4 inj. of dexamethasone, bleeding ulcers were present in all animals. If dexamethasone was continued 4 days longer, the gastric ulcers diminished, and in 20% healing was complete. Free gastric blood was absent, and only 1 rat developed melena. Hemorrhage with melena and stomach distention occurred in 60% of the controls. In both experiments, the diet was limited to water during treatment.

Malabsorption

- 7812 PANCREATIC DAMAGE DUE TO LYMPH CONGESTION: A CAUSE OF MALABSORPTION IN THE PATIENTS WITH INTESTINAL LYMPHANGIECTASIA. (E.) Mizuno, Y. (Osaka U. Sch. Med., Japan), N. Yasuga, K. Sawada, I. Matsumoto, M. Iwasaki, Y. Kayashima, K. Kimura and Y. Kajiyama. Acta Gastroent. Belg. 29(2): 248-259, 1966.

Pancreatic function was studied in 6 patients (age 21-52 yr.) with protein-losing enteropathy among whom diagnosis of intestinal lymphangiectasia was made in 4 and constrictive pericarditis in 2. Lymphangiography of the first 4 patients proved that protein loss was really caused by obstructive or stenotic changes in the thoracic duct as well as in the lymphatic trunks of the intestine. In fact, in one case the disease was completely cured by surgical anastomosis of the pre-stenotic dilated thoracic duct with the vertebral vein. Further studies on the digestive and absorptive capacity of the pancreas showed that the severe malabsorption was not a result of intestinal lymphangiectasia alone, while the gross steatorrhea and azotorrhea strongly suggested concomitant pancreatic insufficiency. Histological studies revealed that this pancreatic insufficiency might be the result of lymph congestion in the pancreatic tissue. In patients with constrictive pericarditis, an elevation of venous pressure was observed in the intestinal wall which may be the cause of protein loss into the lumen.

- 7813 ILEAL BYPASS IN PATIENTS WITH HYPERCHOLESTEROLEMIA AND ATHEROSCLEROSIS. PRELIMINARY REPORT ON THERAPEUTIC POTENTIAL. (E.) Buchwald, H. (U. Minnesota Hosp., Minneapolis) and R. L. Varco. J.A.M.A. 196(7):627-630, 1966.

The procedure consists of transection of the small intestine 200 cm from the ileocecal valve or of a third of the small intestine, whichever is longer. The upper intestinal segment is anastomosed end-to-side with the cecum; the lower section closed by inversion, tacking the closed end to prevent intussusception. This ileal bypass, performed in an attempt to decrease cholesterol absorption, was performed on 18 patients who met the following criteria: severe hypercholesterolemia, clinical signs of atherosclerosis, and a family history of early and severe atherosclerosis; most patients were between 30-50 yr. old; none were over 60. A low-fat diet was begun at least 3 mo. preoperatively and continued postoperatively. Of these patients, 14 had demonstrable coronary heart disease preoperatively (1 had suffered myocardial infarcts but survived the procedure); 1 patient died of a myocardial infarct 4 days postoperatively, while another had a subendocardial infarct after 3 days and recovered. There was no sustained wt. loss; the only type of malabsorption noted, vitamin B₁₂, was corrected by i.m. admin. of the vitamin. No anemia, macrocytosis, or nervous disturbances developed. All the 14 patients evaluated 3 mo. postoperatively showed an av. 40% reduction in serum cholesterol values; about 50% of the group showed cholesterol levels below 200 mg/100 ml. Preliminary clinical evaluation (only 5 patients have been followed up for 2 yr. or more) indicated subjective relief of anginal symptoms, objective regression of xanthomas, and arrested progression of the arterial disease (determined by coronary and femoral angiography).

- 7814 GLUTEN ENTEROPATHY AND SKELETAL DISEASE. (E.). Ross, J. R. (Lahey Clin. Found., Boston, Mass.), S. P. Gibb, D. E. Hoffman, E. P. Clerkin, W. E. Dotter and L. M. Hurxthal. J.A.M.A. 196(3):270-274, 1966.

The symptoms and signs of gluten enteropathy (nontropical sprue) in 42 patients are tabulated. Vitamin D and calcium malabsorption, present in all cases, often led to bone changes; 67% had iron deficiency and macrocytic anemia due to folic acid and iron malabsorption. Calcium malabsorption was present in 48%; many patients had several types of malabsorption (especially fat, carbohydrate, and protein). Small intestinal X-ray pictures were abnormal in 86% (36 cases) but normal in the other 14% (6 cases). The most reliable test was D-xylose absorption; urinary and blood D-xylose tests were abnormal in 69% and 55% of the group, resp., and normal in 19% and 31%, resp. (the others were not tested). Fecal fat excretion was abnormal in 45%, but normal in 24%; this test is not specific for small intestinal disease.

Confirmation of diagnostic accuracy of the history, X-ray, D-xylose, and fecal fat tests was indicated by a favorable response to a gluten-restricted diet.

- 7815 GLUTEN ENTEROPATHY APPEARING AFTER GASTRIC SURGERY. (E.) Hedberg, C. A. (U. Chicago, Ill.), C. S. Melnyk and C. F. Johnson. Gastroenterology 50(6):796-804, 1966.

Four patients who underwent Billroth II partial gastrectomy (2), gastroenterostomy with vagotomy (1), or simple gastroenterostomy (1) for duodenal (3) or benign gastric (1) ulcers, developed very severe and potentially fatal symptoms of gluten enteropathy (including wt. loss of over 20%) almost immediately after surgery. Two of these patients had shown no signs of malabsorption before operation, although 1 had always been of below normal wt.; 1 had a 7-yr. history of distention, diarrhea, and gradual wt. loss; the fourth patient, with a suggestive family history, had also apparently had spontaneously remitting celiac disease in childhood. One patient underwent correction of an afferent loop obstruction, and another underwent 3 further procedures to correct an initially inadequate operation, but the malabsorption symptoms were not alleviated in either case. All patients were treated with a gluten-free diet, with good-to-excellent responses; jejunal histology returned to nearly normal in 3 patients and was improved in the fourth. It is suggested that small intestinal function should be evaluated before gastric surgery in patients with personal or family histories suggesting a malabsorption syndrome.

- 7816 ALBUMIN METABOLISM IN PATIENTS WITH WHIPPLE'S DISEASE. (E.) Laster, L. (NIH, Bethesda, Md.), T. A. Waldmann, L. F. Fenster and J. W. Singleton. J. Clin. Invest. 45(5):637-644, 1966.

Gastrointestinal protein loss in 7 patients with Whipple's disease was studied by the use of Cr⁵¹-labeled albumin in patients during relapse and in remission following therapy. During relapse, the serum albumin conc. was less than 2.5 g/100 ml in 6 of 7 patients and there was an abnormally high fecal excretion of Cr⁵¹. Turnover studies of iodinated albumin in 4 patients indicated that there was also abnormally high albumin catabolism and confirmed the excessive loss of protein into the gastrointestinal tract. Treatment with antibiotics and/or steroids produced clinical remissions and a rise in the conc. of serum albumin. Determinations of I¹³⁵-labeled albumin and fecal excretion of Cr⁵¹-labeled albumin were normal or nearly normal, indicating a reversal of the exudative enteropathy. In 1 patient values of Cr⁵¹-labeled albumin test went from 5.2% to 0.2% by day 16 of therapy. In one patient in remission, admin. of serum in an iodine solution (Lugol's solution) produced no detectable gastrointestinal protein loss. Results indicate that excessive loss of serum protein into the gastrointestinal tract and absolute and relative impairment of albumin synthesis are significant factors in the pathogenesis of the hypoalbuminemia.

- 7817 ISOLATED LACTASE DEFICIENCY PRODUCING POSTGASTRECTOMY MILK INTOLERANCE. (E.) Welsh, J. D. (U. Oklahoma Med. Ctr., Oklahoma City), R. W. Shaw and A. Walker. Ann. Intern. Med. 64(6):1252-1258, 1966.

Lactose tolerance was studied 1-13 yr. (mean 5.6 yr.) after gastrectomy with gastrojejunum or gastroduodenal anastomosis (in 23 patients) or vagotomy with pyloroplasty (1 patient) for gastroduodenal ulcer. Lactose absorption was normal in 19 patients; assay of intestinal specimens from 13 of these patients showed a mean lactase activity of 42 U (range 16-82 U). Mean max. blood sugar increase after lactose admin. in these patients was 110 mg/100 ml (range 38-191 mg/100 ml). The other 5 patients showed abnormal lactose absorption, with a mean blood sugar increase of 4 mg/100 ml and a mean intestinal lactase activity of 6 U. This isolated lactase deficiency was not attributable to any difference in surgical procedure. There were no differences between the groups with respect to intestinal sucrase, maltase, galactinase, or alkaline phosphatase activities, glucose or glucose plus galactose tolerance, or D-xylose excretion tests. Two patients with lactase deficiency had steatorrhea, but the relationship between the 2 conditions, if any, is unknown.

- 7818 COEXISTENT PERNICIOUS ANEMIA AND MALABSORPTION IN FOUR PATIENTS. INCLUDING ONE WHOSE MALABSORPTION DISAPPEARED WITH VITAMIN B₁₂ THERAPY. (E.)

Brody, E. A. (Mt. Sinai Hosp., New York, N. Y.), S. Estren and V. Herbert. Ann. Intern. Med. 64(6):1246-1251, 1966.

Addition of an in vitro intrinsic factor assay to the battery of routine tests for evaluation of malabsorption identified the presence of pernicious anemia with vitamin B₁₂ malabsorption and small intestinal lesions in 4 of 9 consecutive patients with megaloblastic anemia and generalized malabsorption. Malabsorption was due to sprue in 1 patient, jejunal diverticuli in another, and an old side-to-side entero-enterostomy with excluded ileal loop (performed 23 yr. previously for intestinal obstruction). The Schilling test with intrinsic factor remained abnormally low after 9 yr. of parenteral vitamin B₁₂ admin. in the patient with the blind loop. There was no small intestinal lesion in the fourth patient, who had received vitamin B₁₂ just before admission. In this patient, there was no urinary excretion or radioactivity after p.o. admin. of labeled vitamin B₁₂ (with or without intrinsic factor), but after 10 mo. of parenteral vitamin B₁₂ (100 µg every 7-12 days), the Schilling test with intrinsic factor rose to 6.4% and the D-xylose excretion test was normal. This patient may have had pernicious anemia only, with the malabsorption syndrome (vitamins A and B₁₂ and D-xylose) being secondary to intestinal vitamin B₁₂ deficiency. It is concluded that pernicious anemia may be fairly common in malabsorption syndromes, that generalized malabsorption may sometimes be a sequel to vitamin B₁₂ deficiency, and that an in vitro assay of intrinsic factor in the gastric juice should be mandatory in patients with malabsorption.

7819 A STUDY OF "SPRUE SYNDROME IN ADULTS" IN NORTHERN INDIA. (E.) Tandon, B. N. (Chittaramjan Hosp., Calcutta, India), K. Prabhawati Iyenger, M. G. Deo and A. K. Saraya. J. Assn. Physicians India 14(4):197-202, 1966.

In 22 healthy Indian men with normal D-xylose and fat excretion test results, jejuna biopsy demonstrated a mixed pattern of leafy and tongue-shaped villi with only occasional finger-like villi. Of 38 patients with classical clinical features of the sprue syndrome, 63.5% showed steatorrhea and only 18.5% showed defective D-xylose absorption. Jejunal histology was abnormal in 26 cases, but Grade II or III villus atrophy was seen in only 5 and 9 patients, resp. Hematological changes were unusually slight; 41% had no anemia and 23% had only mild anemia (hemoglobin 10-12 g%) although the mean duration of disease in these patients was 6.5 yr. Megaloblastic changes were seen in the bone marrow of 4 of 8 patients examined, but folic acid therapy gave satisfactory responses in only 5 of 10 cases. None of the patients responded to a gluten-free diet. This sprue syndrome was therefore not due to celiac disease and did not show a complete resemblance to tropical sprue; the authors suggest the term "idiopathic tropical malabsorption syndrome," and recommend further investigation of such possible causes as diet, infection, and intestinal parasites.

7820 BACTERIOLOGICAL STUDY OF SMALL INTESTINAL FLUID IN TROPICAL SPRUE. (E.) Desai, H. G. (Tata Mem. Hosp., Parel, Bombay, India), D. V. Parekh and K. N. Jeejeebhoy. J. Assn. Physicians India 14(4):203-205, 1966.

Jejunal fluid was collected from 28 patients with tropical sprue (using means to prevent contamination with oropharyngeal bacteria). The small intestinal fluid was sterile in 16 patients. Fluid from the other 12 patients grew bacteria upon culture but only 4 samples showed bacteria upon direct smear. Bacterial counts were generally low (under 6000/ml) in all but 4 patients; 2 patients had a somewhat heavier count of Streptococcus faecalis and Escherichia coli (6000-30,000/ml) and the other 2 specimens grew Bacillus pyocyaneus (6000-50,000/ml). There was no significant difference in absorption studies between patients with and without bacteria in the upper jejunum.

7821 SOME OBSERVATIONS ON MALABSORPTION IN CHRONIC AMOEBIASIS. (E.) Misra, S. S. (King George's Med. Coll., Lucknow, India), P. S. Misra and V. C. Agarwal. J. Assn. Physicians India 14(4):207-215, 1966.

A typical malabsorption syndrome was found in 9 of 70 patients with amebiasis. These 9 cases all showed intestinal involvement without liver involvement. The duration of disease was 1-over 5 yr. in all but 1 patient; symptoms such as lassitude, wt. loss, general anasarca, glossitis, stomatitis, cheilosis, angular stomatitis, skin

changes, and tenderness and thickening of the descending colon, were more frequently encountered in this group than in the 61 patients without steatorrhea. All 9 patients showed obvious vitamin B deficiency; 5 showed non-specific inflammatory changes in the small intestinal mucosa. Possible causes of this malabsorption (mucus losses leading to defective fat absorption; vitamin B deficiency; increased endogenous fat loss due to diffuse intestinal inflammation with excessive loss of epithelial cells; lymphatic obstruction) are discussed. It is concluded that malabsorption in amebiasis probably arises from multiple causes.

- 822 GASTROINTESTINAL PROTEIN LOSS MEASURED WITH ^{59}Fe -LABELLED IRON-DEXTRAN. (E.) Andersen, S. B. (Royal Hosp., Copenhagen, Denmark) and S. Jarnum. Lancet 1(7446):1060-1062, 1966.

Studies of excretion of ^{59}Fe -iron dextran (I) in 7 control patients without gastrointestinal protein loss demonstrated that an oral dose was excreted in the feces (51-105%) and essentially none was lost in the urine. On i.v. admin. in 6 control patients less than 1% was excreted in the feces (0.2-0.7) or urine (0.0-0.7). In patients with gastrointestinal protein loss (regional enteritis, ulcerative colitis, exudative enteropathy, sprue), 1-13.8% of a dose of I was found in the feces and less than 1% (0.0-0.4) in the urine. Simultaneous studies of gastrointestinal protein loss with I and Cr^{51} -albumin showed that the two methods were in close agreement and plasma volume determinations using I were not significantly different from those using Evans Blue dye or ^{131}I -albumin. The I method had the advantages over ^{131}I -polyvinylpyrrolidone or Cr^{51} -albumin in that the iron was not excreted into the urine and could be used to determine gastrointestinal protein loss in patients who could not keep urine and feces separate.

- 823 THE ROLE OF ALTERED BILE ACID METABOLISM IN THE STEATORRHEA OF EXPERIMENTAL BLIND LOOP. (E.) Kim, Y. S. (Cornell U. Med. Coll., New York, N. Y.), N. Spritz, M. Blum, J. Terz and P. Sherlock. J. Clin. Invest. 45(6): 956-962, 1966.

Steatorrhea of up to 56% of dietary fat was demonstrable in dogs within 2-7 mo. after construction of a self-filling blind intestinal loop approx. 5 cm below the ligament of Treitz. In the fasting jejunal content of dogs with significant steatorrhea, following i.v. admin. of cholesterol labeled with radioactive carbon, bile acid conjugation was sharply reduced as compared to controls, although bile acid conjugation in the gallbladder remained at normal levels. After instillation of conjugated biliary bile acids from a normal dog into the isolated blind loop, a high percentage of deconjugated bile acids was found within a few hr., accompanied by conversion of conjugated acids into mono- and dihydroxy forms, indicating alteration of the conjugating structure. Similar changes occurring in the jejunal content outside the loop may have been due to extension of bacterial overgrowth from the latter. Formation of micellar lipid was grossly defective in the jejunal content below the blind loop. Steatorrhea, following intragastric instillation of a liquid meal containing safflower oil, although total lipid concentration was comparable to that of the controls. Arrest of wt. loss and a marked reduction of fecal fat loss followed daily p.o. admin. of tetracycline. A similar result could be obtained by feeding of sodium taurocholate, although these induced diarrhea. It is concluded that the altered bile acid metabolism in these animals played an important role in the impairment of fat absorption, probably by interfering with intraluminal micelle formation.

- 824 RESIDUAL ACTIVITY OF DEFECTIVE ENZYMES IN HEREDITARY MALABSORPTION OF MONO- AND DISACCHARIDES. (Ger.) Linneweh, F. (U. Marburg, Germany), E. Schaumlöffel, E. H. Graul and H. H. Bode. Schweiz. Med. Wschr. 96(13):424-427, 1966.

Glucose and galactose soln., labeled with radioactive carbon, were admin. at different times to a child with a suspected, genetically-determined insufficiency of the glucose- and galactose-resorbing transport mechanisms of the intestinal tract. Determinations of serum, urinary and fecal activities, as compared to those found in a normal child of the same age, indicated that the patient was able to resorb only 0.6% of the normally-expected amount of glucose and 4.56% of the normally-expected amount of galactose. Similar resorption tests, admin. to 2 sisters, aged 1 and

SMALL BOWEL

Malabsorption

6 3/4, confirmed normal resorption of lactose, glucose and galactose, although sucrose resorption was only 7.14% and 10.7% of normal expectation, resp. Resorption of isomaltose was also defective in these siblings. The resorption data were used to determine the amount of sugar which these patients could tolerate in their diets.

- 7825 MALABSORPTION IN INTESTINAL SCLERODERMA. CORRECTION BY ANTIBIOTICS. (E.) Kahn, I. V. (Cornell U. Coll. Med., New York, N. Y.), G. H. Jeffrie and M. H. Sleisenger. New Eng. J. Med. 274(24):1339-1344, 1966.

Malabsorption developed in 4 patients 4-15 yr. after the onset of peripheral and esophageal symptoms of disseminated scleroderma. None showed clinical symptoms of vitamin or mineral deficiency or of hypoproteinemia; only the most sensitive absorption tests (fecal fat and D-xylose excretion) were able to establish the presence of malabsorption. Bacterial proliferation in the duodenal lumen was suggested by an increased excretion of indican, and confirmed by duodenal fluid culture, in 3 cases. Treatment with tetracycline (1 g/day) caused rapid and marked improvement in the symptoms and absorption studies in 3 patients; 2 of these patients gained wt. and were able to resume their normal activities. Two patients had been maintained in good condition on broad-spectrum antibiotics for 9 and 18 mo. at the time of report, but the development of resistance necessitated periodic changes in the antibiotics admin. Tetracycline, oxytetracycline, and ampicillin were the most effective; kanamycin, neomycin, paromomycin, chloramphenicol, and sulfisoxazole were less effective. One patient failed to respond to tetracycline, ampicillin, and neomycin. It is concluded that long-term treatment with broad-spectrum antibiotics may be effective in patients with malabsorption secondary to intestinal scleroderma.

- 7826 CARBOHYDRATE STUDIES IN TROPICAL SPRUE. (E.) Sheehy, T. W. (Walter Reed Inst. Res., Washington, D. C.), P. R. Anderson and B. E. Baggs. Am. J. Dig. Dis. 11(6):461-473, 1966.

Glucose, lactose, sucrose, and galactose tolerance tests, D-xylose excretion, and (in some patients) jejunal disaccharidase activities were tested in 34 patients with untreated tropical sprue, 20 normal subjects, and 18 sprue patients whose anemia had been alleviated and who were relatively symptom-free after 2-4 yr. of treatment with vitamin B₁₂ or folic acid. In the glucose tolerance test, blood sugar levels exceeded fasting levels by 25 and 40 mg/100 ml in 82% and 60%, resp., of 20 normal controls, compared to 25% and 10%, resp., of 20 untreated sprue patients. Similar results of the lactose tolerance test were 100% and 90%, resp., in controls, compared to 5% and 0%, resp., in 20 patients with sprue. In the sucrose tolerance test the results were 100% and 100%, resp., in normal controls, compared to 75% and 30%, resp., in 20 sprue patients. A flat lactose tolerance test was associated with persistent steatorrhea in 5 treated sprue patients; 1 treated patient, without malabsorption, also had a flat curve, but the other 3 treated patients without sprue showed normal lactose tolerance curves. The mean max. blood glucose increases after lactose admin. in normal subjects and untreated sprue were 53.3 and 7.5 mg/100 ml resp. In the lactose tolerance test using 1.5 g/kg (p.o.), if the normal response was defined as an increase of 25 mg/100 ml, all the normal controls but only 1 of the 20 untreated sprue patients showed normal responses. If the normal response was defined as an increase of 40 mg/100 ml, all but 1 of the controls and none of the sprue patients showed normal responses. Mild distress developed in about 50% of the sprue patients admin. lactose, but was not so severe that the test had to be discontinued. Mean disaccharidase activities (in disaccharidase U/g wet wt.) in normal subjects and sprue patients were: lactase 7.4 and 0.06-0.56; sucrase 16.5 and 0.2-13.5; and maltase 48.7 and 0.9-44.5, resp. It is concluded that the lactose tolerance test is more useful than the glucose, sucrose, or galactose tests in detecting tropical sprue and monitoring its course.

- 7827 MONOSACCHARIDE MALABSORPTION IN YOUNG INFANTS. (E.) Burke, V. (Royal Child. Hosp., Melbourne, Australia) and D. M. Danks. Lancet 1(7448):1177-1180, 1966.

Four cases of complete failure of intestinal absorption of glucose, galactose and fructose are reported, all occurring in young, female infants who also showed

vere, asymptomatic hyperchloremic acidosis. Symptoms of the malabsorption syndrome were first observed several days or wk. after birth, and were preceded, in 4 of 4 cases, by episodes of what appeared to be infective diarrhea. The disorder was transient in all cases, lasting 2 wk.-5 mo.; did not appear to involve the transport mechanisms specifically involved in monosaccharide absorption; and did not appear to involve any determinable genetic factor. Duodenal mucosa derived by peroral biopsy was normal in all four cases, with normal levels of activity of all disaccharidases. In the infant with the most prolonged illness, renal tubular function was also disturbed transiently. Life was preserved by a sugar-free diet, supplemented by vitamins and electrolytes, and diarrhea was controlled by a mixture of casein and butter fat, emulsified by deoxycholate. Recovery was spontaneous. The authors speculate concerning the possibility of the presence of abnormal bacterial flora in the duodenum or the upper intestinal tract.

LARGE BOWEL

- 7841 DIVERTICULITIS: A FOLLOW-UP OF 100 CASES. (E.) Bolt, D. E. (West Middlesex Hosp., London) and L. E. Hughes. Brit. Med. J. 1(5497):1205-1209 1966.

Follow-up studies of approx. 5-15 yr. were conducted in 100 consecutive cases treated for diverticulitis of the colon. Fifty-two patients presented as emergency cases with acute diverticulitis and varying degrees of peritonitis and were operated within 24 hr.; surgical treatment consisted of laparotomy (with or without drainage and/or suture; 64%) or laparotomy with colostomy (36%); 7 patients were treated by early but not immediate resection; results (5-15 yr.) included no recurrence (26 patients), recurrence (13), death in initial attack (7), and incomplete follow-up (6). If early deaths, cases treated by resection, and those lost to follow-up are excluded, 33 patients remain for long term assessment; of these, 20 (61%) had no need to consult their doctors for bowel symptoms since discharge and 13 (39%) had further diverticulitis. Long term results according to type of operation showed a higher recurrence rate (32%) for simple laparotomy, although recurrences were mild or solitary episodes; 50% recurrence was seen in patients subjected to colostomy without resection; only 1 of 7 patients treated by resection had recurrence. Three of 100 patients presented with colonic bleeding and none had recurrence after surgical treatment. Of 37 patients subjected to interval surgery, 32 were treated by resection (20; 1 recurrence), simple laparotomy (9; 4 recurrences), colostomy without resection (2; both had recurrences), or permanent colostomy (1; with recurrence). In 7 patients with fistula in diverticulitis, treatment was by resection (3; 1 recurrence and death), simple closure (1; with recurrence), colostomy without resection (1; with recurrence); no recurrence occurred in 2 patients who refused surgery. Of 8 patients presenting with acute intestinal obstruction, 1 survived until death from unrelated cause after ileo-transverse anastomosis, 2 were symptomless for 6-13 yr. after resection, while 1 was lost to follow-up after 3 yr. of good health and 1 had recurrence following permanent colostomy.

- 7842 ACUTE LARGE-BOWEL OBSTRUCTION: AETIOLOGY AND MORTALITY. (E.) Carden, A. B. G. (Royal Melbourne Hosp., Australia). Med. J. Aust. 1(16):662-663, 1966.

The etiology and mortality of acute large bowel obstruction (371 patients; 67%) was studied in a series of 554 patients treated from 1932-61. Overall mortality was 34%. The most frequent cause of obstruction was carcinoma of the colon and rectum; mortality rate in this group was 39.4%; distribution of carcinomas presenting as large bowel obstruction included splenic flexure, descending, and sigmoid colon (76%), rectum and rectosigmoid (21.5%), and hepatic flexure (1.9%). Other causes of large bowel obstruction were sigmoid volvulus (9%; mortality 42%); diverticulitis (7%; mortality 14%); fecal impaction (4.6%; mortality 7.1%); miscellaneous, including peritoneal carcinomatosis, tuberculosis of the colon, endometriosis, adhesions, gallstone obstruction, melanoma and leiomyosarcoma, and megacolon (8%; mortality 29.6%), and undiagnosed conditions (4.5%; mortality 12%). The incidence and mortality of large bowel obstruction has declined in recent yr., as seen by the fact that from 1952-61 only 82 patients were treated and 17% mortality occurred, while in the 472 cases observed from 1932-51, mortality was 37%.

- 7843 VILLOUS TUMORS OF THE COLON. (Ger.) Kügler, S. (U. Hamburg, Germany). Langenbeck. Arch. Klin. Chir. 314(2):149-164, 1966.

In 1959-1965, 30 patients with villous colon tumors were treated. All patients showed melena or mucous discharges or both; the duration of symptoms was 3 mo.-5 yr. Watery diarrhea was present in some cases. Melena was absent in 5 patients and slight in 2 others, all of whom had large tumors (av. diameter over 10 cm); all 8 patients with small tumors (av. diameter up to 2 cm) had melena without discharge of mucus. Electrocoagulation or local excision of the tumor was performed in 9 cases; 9 patients underwent proctotomy; colon or rectum amputation with anus praeter formation was performed in 7 cases, and the other patients underwent transabdominal resection and Babcock's procedure. There were 3 recurrences; 1 patient developed

LARGE BOWEL

recurrent tumors, 1 and 2 yr. after the initial resection. In 2 of these patients, the recurrent tumors were adenocarcinomas. Histological classification of these villous tumors as adenomas, benign villous tumors, or adenocarcinomas, was very difficult. There was a great discrepancy between the histological appearance and the clinical behavior (especially the high tendency to recurrence) of these tumors; despite their histological anaplasia, their biological behavior was relatively benign. One case history of a patient showing marked protein and electrolyte loss is given.

344 COLOSTOMIES AND THEIR COMPLICATIONS. (E.) Green, E. W. (State U. Iowa, Iowa City). Surg. Gynec. Obstet. 122(6):1230-1232, 1966.
From 1958-63, 318 colostomies (12 loop and 88 divided limb of the sigmoid colon; 48 loop and 69 divided limb of the transverse colon; 1 ascending colon colostomy) were performed in 297 patients. The overall complication rate was 21.7%, while 5.4% had complications which required operative correction. The most common complications were prolapse (25%), intestinal necrosis (17%), retraction of stoma (13%); other complications included wound evisceration, wound infection, wound hernia, stenosis (6%), intestinal obstruction (5%), and fecal fistula. Complications were more frequent when the loop colostomy of the sigmoid or transverse colon was brought through the exploratory wound instead of through a separate wound. Complications occurred in 39% of patients subjected to colostomy for benign lesions. A high complication rate was observed in patients under 10 yr. old.

345 EFFECTS OF VARIOUS SOYBEAN PRODUCTS ON FLATULENCE IN THE ADULT MAN. (E.) Steggerda, F. R. (U. Illinois, Urbana), E. A. Richards and J. J. Rackis. Proc. Soc. Exp. Biol. Med. 121(4):1235-1239, 1966.
In 4 human male subjects kept on a carefully controlled diet (2,334 calories/day) to which various fractions of soybean meal (146 g/day) were added, results indicated that only the low molecular wt. meal constituents produced flatus. When soy protein conc. and sodium soy proteinate were consumed, the protein seemed to have an inhibitory effect on the flatus-producing mechanism. Soybean hulls, fat and water-insoluble polysaccharides were not associated with flatulence production to any significant degree. Upon feeding of equivalent amounts of navy bean meal, flatus vol. increased 2.52 times compared to that observed following consumption of dehulled, defatted soybean meal.

346 STUDIES OF CUPRIFEROUS CELLS IN THE RECTAL MUCOSA IN MELANOSIS COLI. (Ger.) Böllükoglu, M. A. (U. Erlangen-Nurnberg, Germany), K. Heinkel, J. Landgrad and K. Elster. Zschr. Gastroent. 4(1):22-26, 1966.
The presence of cupriferous cells in the rectal mucosa was demonstrated histologically in tissue samples treated with p-dimethylamine-benzylidene-rhodanine, both in 4 of 26 autopsied subjects with accumulations of pigment deposits in these tissues and in 39 of 43 autopsied controls. In both instances, all tissue samples showing eosinophilia also showed the presence of numerous cupriferous cells, although the rectal mucosa of subjects with melanosis coli was usually free of indications of chronic irritation, in contrast to that of controls. The authors conclude that there is no relationship between accumulation of pigment deposits in these tissues and the incidence of cupriferous cells.

347 VALUE OF RECTAL BIOPSY IN THE DIAGNOSIS OF PRIMARY SYSTEMIC AMYLOIDOSIS. (E.) Kyle, R. A. (Mayo Clin., Rochester, Minn.), R. J. Spencer and D. C. Dahlin. Am. J. Med. Sci. 251(5):501-506, 1966.
The technique for rectal biopsy is described and its value in the diagnosis of primary systemic amyloidosis assessed. Results were positive in 17 of 20 (85%) patients with primary systemic amyloidosis; in 1 of the remaining 3 patients, amyloidosis was strongly suggested, but the diagnosis was uncertain, and it was classified as negative. Of 3 patients with features of both multiple myeloma and amyloidosis, 2 had a positive rectal biopsy. Amyloid was found in the submucosa in 15 patients and in the mucosa in 4. In 7 of the patients, all of the amyloid was in the vessel walls in various levels of the biopsy specimen. Specimens of 2 of the 3 patients

LARGE BOWEL

with a negative biopsy did not contain submucosal tissue. Rectal biopsy was negative in 79 other patients with such conditions as congestive heart failure, nephrotic syndrome, peripheral neuropathy, multiple myeloma, orthostatic hypotension, intestinal malabsorption, and carpal tunnel syndrome. None of these patients subsequently were proved to have amyloidosis.

- 7848 DETERMINATION OF YIELD PRESSURES: A METHOD FOR MEASURING ANAL SPHINCTER COMPETENCE. (E.) Harris, L. D. (Boston U. Sch. Med. Hosp., Mass.), C. S. Winans and C. E. Pope II. Gastroenterology 50(6):754-760, 1966.

A method is described to measure resting and "augmented yield" pressures (the latter during max. tightening of the sphincter) by inj. or infusion of micro quantities of fluid and using an open-tip apparatus. By determining augmented yield pressures before and after active sphincter contraction, the voluntary and involuntary components of sphincter contraction can be measured separately. Sphincter pressures were measured in this way in 16 normal men and 5 incontinent patients. The av. resting and augmented yield pressures in the normal subjects varied widely (60-100 and 130-300 mm Hg, resp.), but did not overlap with the values obtained in the patients with incompetent sphincters (20-40 and 30-70 mm Hg, resp.).

- 7849 CANCER OF THE COLON, RECTUM AND ANUS: REVIEW OF 1,687 CASES. (E.) Floyd, C. E. (Louisiana State U. Sch. Med., New Orleans), C. T. Stirling and I. Cohn, Jr. Ann. Surg. 163(6):829-837, 1966.

A review of the records of 1687 patients with histologically confirmed colorectal cancers indicated an age range of 1-98 yr. at the time of diagnosis, with peak incidence in the sixth decade and only slightly lower incidence in the decades immediately preceding and following. There was a relatively high incidence of intercurrent diverticulosis, a very low incidence of intercurrent ulcerative colitis. (The latter may have been due to the infrequency of this disease in the New Orleans area.) The lesion involved the colon alone or the colon and regional lymph nodes alone in approx. half the cases. Approx. 80% of the lesions were adenocarcinomas. Treatment was almost exclusively surgical. For the patient group as a whole, 1 yr. survivals were 43%, 5 yr. survivals were 26% and 10 yr. survivals were 18%. Comparable tabulations for patients undergoing radical surgery were 70%, 53% and 39%, resp. The 5-yr. survival rate was 51% for patients with lesions confined to the intestinal wall, 63% for patients with lesions limited to the intestinal mucosa.

- 7850 CHANGING RELATIVE FREQUENCY OF CANCERS OF THE COLON AND RECTUM IN THE UNITED STATES. (E.) Axtell, L. M. (NCI, Bethesda, Md.) and L. Chiazze, Jr. Cancer 19(6):750-754, 1966.

Review of the records of approx. 50,000 Caucasian patients with colorectal cancers, all in hospitals participating in the End Results Program of the National Cancer Institute between 1940-1962, inclusive, indicated a consistent, substantial increase in the frequency of incidence of colonic, as compared to rectal, cancers affecting both men and women. The increase has been particularly clearly evident since 1955. A supplementary study of the age-adjusted incidence rates reported for New York and Connecticut yielded similar results.

- 7851 PRIMARY FISTULECTOMY FOR ANORECTAL ABSCESS: CLINICAL STUDY OF 500 CASES. (E.) McElwain, J. W., R. M. Alexander and M. D. MacLean. Dis. Colon Rectum 9(3):181-185, 1966.

Of 500 patients with anorectal abscesses, 20% had previously undergone surgery for anorectal abscess or fistula. Only 33 had complained of diarrhea before the abscess developed; 44 had received antibiotics before onset of symptoms or in an attempt at treatment of the abscess. The av. duration of symptoms in 469 patients was 1 wk. The procedure performed in all cases was incision and drainage with fistulectomy; 231 patients (46%) underwent other surgical procedures, usually hemorrhoidectomy (single phase in 125 cases, multiple phases in 91). Nine patients had additional fistulas; some had both acute abscess and fistulas, and 1 patient had multiple abscesses and fistulas. The av. healing time was 7 wk.; it would be much less if several patients with very large, difficult lesions had been excluded from the group. Early complications (within 2 wk.) were seen in 9 patients and late

LARGE BOWEL

complications in 13 cases; the overall incidence was 4.4%. The av. follow-up time was 36 mo. (over 3 yr. in 216, over 5 yr. in 143). There were 8 recurrences, 6 within the first 9 mo.

52 AN EXPERIENCE IN BOMBAY WITH POSTOPERATIVE COMPLICATIONS OF HEMORRHOID-ECTOMY. (E.) Menda, R. K. Dis. Colon Rectum 9(3):176-178, 1966.
Methods of treatment of hemorrhoids in 250 patients included ligature in 55 patients, ligature with excision in 185, complete removal of the hemorrhoidal area in 5, and submucous excision of multiple lesions in 5. Pain was the most frequent postoperative complication (200 patients or 80%), but it persisted for more than 7 days in only 21 cases. Urinary retention developed in 135 patients (124 were men). External tags were noted in 105 (71 after ligature with excision), hemorrhages in 9 (early in 2, late in 7), fissures in 6, delayed wound healing (due to either a faulty technic or improper postoperative care) in 7, pruritus ani and perianal dermatitis (these were late complications) in 12, all of whom responded to topical steroids. Abscesses and fistulas developed in 2 patients; 2 patients developed recurrences. Strictures developed in an unspecified number of cases, usually because of faulty technic and lack of postoperative care. Most postoperative complications can be avoided by use of the proper surgical method. Whitehead's operation is not recommended, because it almost always results in ectropion or anastomotic strictures.

53 THE CONE-SHAPED SEGMENT IN THE DIAGNOSIS OF HIRSCHSPRUNG'S DISEASE. (E.) Mouton, R. A. (Louisiana State U. Sch. Med., New Orleans), R. Spencer, C. M. Nice, Jr. and V. R. Croft. Southern Med. J. 59(6):707-712, 1966.
The cone-shaped segment, between the normal, dilated bowel and the collapsed, aganglionic portion, was a constant X-ray finding among 13 young children with histologically confirmed Hirschsprung's disease and 4 in whom biopsy or autopsy were not performed, despite apparent confirmation of diagnosis via the gross configuration of the colon. The phenomenon was also apparent in X-rays of the gas-filled colons of 2 other infants in whom the disease was confirmed, although no barium enema had been given. Among 18 children with symptoms suggestive of Hirschsprung's disease but no abnormal findings on barium enema, all became free of the symptoms in question. The authors conclude that the cone-shaped segment they describe may be a specific X-ray indication of the presence of this disorder.

Ulcerative Colitis

- 7920 TREATMENT OF ULCERATIVE COLITIS WITH ANTIMETABOLITES. (E.) Bean, R. H. D. (Repatiation Gen. Hosp., Heidelberg, Victoria, Australia). Brit. Med. J. 1(5495):1081-1084, 1966.

Treatment with antimetabolites (6-mercaptopurine, busulfan, 6-thioguanine) was evaluated in 7 male patients (age 40-57 yr.) with ulcerative colitis. Consistent improvement in peripheral blood (hemoglobin rise and platelet increase), serum proteins, bowel habits, barium-enema examinations, and rectal biopsy findings was observed, but only as long as therapy continued. 6-Mercaptopurine was admin. to 6 of 7 patients and appeared to be the safest and most predictable agent to use; relapse was treated by 300 mg/day, while 25-75 mg/day were sufficient for maintenance; some degree of bone marrow depression occurred and 2 patients had abnormal liver function tests, but no further reactions were seen when corticosteroids were also admin. Two patients treated with long term 6-thioguanine developed neurological manifestations, and the drug was abandoned. Busulfan (100 mg) was admin. at long intervals in 3 patients and remission lasting 3 to more than 12 mo. occurred; because of the 3-4 wk. delay between admin. and effect, this drug was not suitable for treatment of relapse. Until further testing, the author feels it wise to restrict the use of these drugs to patients in the older age group in whom surgery is contraindicated or refused. Disappointing features are failure to achieve cure and severity of relapse upon suspension of treatment. The role of the platelet in ulcerative colitis is discussed, and observations support a viral rather than autoimmune basis for the disease.

- 7921 ILEOANASTOMOSIS WITH INTERPOSITION OF AN ANTIPERISTALTIC SECTION OF SMALL INTESTINE, FOLLOWING COLECTOMY IN A PATIENT WITH ULCERATIVE COLITIS. (Ger.) Oppolzer, R. (Vienna Gen. Hosp., Vienna, Austria). Chirurg 37(5):219-221, 1966.

In a patient with fulminating, toxic-septic, ulcerative colitis involving the left half of the colon as far as the rectum (and complicated by multiple ulcerations and fistulae in the rectum), a left hemicolectomy was followed by eversion of the rectum out of the anus, resection to within approx. 5 cm of the anus, and curettage of the rectal mucosa which remained. In subsequent surgery, the anus was joined to an antiperistaltic section of the ileum, derived originally from the area just below the ileocecal valve. This, in turn, was joined to a section of ileum exhibiting normal peristaltic action and anastomosed to the (displaced) transverse colon. The antiperistaltic section served effectively to delay the passage of stools until sufficient volume and pressure had developed to overcome its resistance to them and effect an essentially normal evacuation.

- 7922 THREE HUNDRED CASES OF DIFFUSE ULCERATIVE COLITIS TREATED BY TOTAL COLECTOMY AND ILEO-RECTAL ANASTOMOSIS. (E.) Aylett, S. O. (Westminster Hosp., London). Brit. Med. J. 1(5494):1001-1005, 1966.

Total colectomy with ileorectal anastomosis was performed in 131 male and 169 female patients (including 16 children under 15) with ulcerative colitis. The overall operative mortality was 5.7% (17 patients); 17% in fulminating cases, 3.7% in acute cases, and 2.7% in chronic cases; there were also 10 non-operative deaths. Conversion to ileostomy was required in 14 cases (5% of the survivors); 250 of the 259 remaining patients were in normal health up to 13 yr. later.

- 7923 LIVER FUNCTION AND HISTOLOGY IN PATIENTS WITH NON-SPECIFIC HEMORRHAGIC PROCTOCOLITIS (HEMORRHAGIC PROCTITIS AND ULCERATIVE COLITIS). (Dan.) Anthonisen, P. (Glostrup Hosp., Denmark), P. Christoffersen, P. Riis, K. Schourup and M. Schwartz. Ugeskr. Laeg. 128(16):471-478, 1966.

When 55 patients with non-specific hemorrhagic proctocolitis underwent liver biopsy, approx. half showed round-cell infiltration of the biliary ducts and/or the immediately surrounding parenchyma, in the absence of any disorder usually associated with such infiltration. Infiltrations consisted primarily of lymphocytes, although reticulum cells (especially, proliferating Kupffer's cells) and eosinophilic

neutrophils were seen occasionally. Necrotic cells, infiltration of the parenchyma, incipient or established cirrhosis were not found. Four patients showed mild fatty degeneration, but only 1 (who had undergone total proctocolectomy 7 yr. previously) had an abnormal liver tolerance test. There was no correlation between infiltration and sex, age, extent of the spread of the disorder in the intestine, severity or duration of illness. In 4 of 22 biopsies classified as abnormal in foregoing terms and in 1 of 33 classified as normal, only very slight changes were involved; in 18 of 22 and 32 of 33, resp., identical classifications resulted from subsequent, independent, "blind" study. The authors conclude that the infiltrative process in question is a secondary complication in hemorrhagic proctocolitis, rather than a primary component of the disorder.

- 24 LONG-TERM PROGNOSIS OF ULCERATIVE COLITIS. (E.) Watts, J. McK. (Gen. Infirm., Leeds, England), F. T. De Dombal, G. Watkinson and J. C. Goligher. Brit. Med. J. 1(5501):1447-1453, 1966.

A survey of 465 ulcerative colitis patients followed over periods of 1-10 yr. (see 7925) confirmed that the subsequent course of the disorder was not affected by the duration of symptoms, the extent of the colitis at the time of first attack, or the degree of severity of the first attack. Both the relative severity of attacks and the proportion of medical failures were greater before the age of 20 and after 60 than they were in the years intervening. Approx. half the total number of patients were spent in remission. Among patients with total colorectal involvement, the mortality rate was 2.0-2.2% per annum in all age groups below 60. After 60, the mortality rate rose abruptly to 11.1%. The authors conclude that the presence of extensive ulcerative colitis in patients aged 60 or more is a definite indication for prophylactic proctocolectomy.

- 25 LOCAL COMPLICATIONS OF ULCERATIVE COLITIS: STRICTURE, PSEUDOPOLYPOSIS, AND CARCINOMA OF COLON AND RECTUM. (E.) De Dombal, F. T. (Gen. Infirm., Leeds, England), J. McK. Watts, G. Watkinson and J. C. Goligher. Brit. Med. J. 1(5501):1442-1447, 1966.

A survey of 465 patients with ulcerative colitis (see also 7924) indicated that 11.2% suffered from stricture of the colon or rectum, 12.5% from pseudopolyposis and 1.7% from invasive carcinoma of the colon or rectum. The incidence of stricture was directly proportional to the amount of the tract involved in the colitis, with stricture already developed in more than 17% of the patients with total colorectal involvement. (Approx. 25% of the patients coming to surgery showed stricture at the time.) The incidence of pseudopolyposis showed a similar relationship to the extent of colorectal involvement. Statistical analysis of the data provided by the patient group as a whole indicated the cumulative, expected incidence of carcinoma after 25 yr. of colitic symptoms was 25.8%; in the subgroup of patients who developed total colorectal involvement, it rose to 41.8% after 25 yr. of colitic symptoms. The observed mortality rate due to carcinoma (all patients) was 11 times normal expectation for the population at large. Prophylactic proctocolectomy is accordingly strongly recommended for patients with total colorectal involvement after 10 yr. duration of colitic symptoms.

- 26 INCIDENCE AND MANAGEMENT OF ANORECTAL ABSCESS, FISTULA AND FISSURE, IN PATIENTS WITH ULCERATIVE COLITIS. (E.) De Dombal, F. T. (Gen. Infirm., Leeds, England), J. McK. Watts, G. Watkinson and J. C. Goligher. Dis. Colon Rectum 9(3):201-206, 1966.

Various anorectal complications (abscess, fistula or fissure-in-ano, rectovaginal fistula, etc.) were noted in 82 (17.6%) of 465 patients with ulcerative colitis. The incidence of fissure-in-ano was significantly greater in patients with severe colitis or with disease involving the entire colon and rectum; the incidence of the other complications was about the same regardless of the severity or extent of the disease. All complications were most frequent during the first yr. after onset. Perianal abscesses were always treated by incision and drainage, while rectovaginal fistulas required excision. Fissure-in-ano was treated symptomatically; spontaneous healing of fistula-in-ano was noted in 6 cases. The primary disease itself required vigorous treatment.

EXOCRINE PANCREAS

9 EXPLORATION OF PANCREATIC FUNCTION BY MEANS OF THE SERUM GLUCOSE-AMYLASE TEST. (Fr.) Ermini, M. (U. Rome). Presse Med. 74(21):1079-1081, 1966. Pancreatic function was assessed by determination of serum amylase after p.o. administration of glucose (0.7 g/kg) in 45 subjects with no apparent pancreatic disease and 41 patients with chronic pancreatitis or pancreatic cancer. Among subjects with no apparent pancreatic disease, response was negative in 40 (89%) and positive in 5; subsequent surgery in the 5 positive subjects revealed cholelithiasis in 4 and duodenal ulcer in 1. Among patients with pancreatic diseases, response was positive in 37 of 41 (90%); of these, positive response was observed in all 22 patients with chronic pancreatitis and in 15 of 19 patients with pancreatic carcinoma. Among the advantages of this method of evaluation of pancreatic function are agreement with surgical findings in 90% of the cases, practically absolute specificity with regard to pancreatic function (pancreatic involvement was excluded in 2 patients with cancer of the choledochus, 2 with primary cancer of the liver, and 2 with malabsorption syndrome), and sensitivity in the detection of even less severe pancreatic lesions.

10 PANCREATOGRAPHY. (Fr.) Mercadier, M. (15 Greuze St., Paris) and P. Clot. Acta Gastroent. Belg. 29(2):211-215, 1966. The authors review various pancreatographic techniques (retrograde pancreatography, ascending pancreatography, and cystography) and assess their value in several pancreatic diseases. In acute pancreatitis, moderate reflux into the pancreatic duct is frequent during radiomanometry; the authors believe that pancreatography during the course of acute pancreatitis is dangerous, even though dilatation of the pancreatic duct is often revealed; in most cases, however, this method fails to reveal alterations of the pancreatic ducts. On the contrary, in chronic pancreatitis, pancreatography revealed dilatation of the pancreatic duct in 1 of 62 patients with non-calcifying chronic pancreatitis with biliary lithiasis; in 7 of 14 patients with non-calcifying chronic pancreatitis (in 14 patients, sclerotic narrowing of the pancreatic ducts was observed); in 50 of 55 patients with calcifying chronic pancreatitis; in 4 of 4 patients with pancreatic lithiasis associated with biliary lithiasis. The fundamental importance of pancreatography in chronic pancreatitis is stressed. The value of cystography lies in the fact that precise relations as to volume, connections with adjacent organs, and the formation of pseudocysts are possible; in the authors' series, communication between the cyst and pancreatic duct was evident in 28 pseudocysts but was not evident in 49 pseudocysts. Pancreatography is of little value in the diagnosis of benign and malignant tumors of the pancreas, except in the differential diagnosis of chronic pancreatitis.

CONGESTIVE PSEUDOLOBULATION OF THE PANCREAS. (E.) Polanco, G. B. (Jewish Hosp., Cincinnati, Ohio), R. Stern and E. Polanco. Arch. Path. (Chicago) 81(6):558-562, 1966. Sections of pancreas obtained from 3,500 autopsies were examined for the presence or absence of congestive pseudolobulation. The lesion was observed in 60 (1.7%) cases; changes were marked in 17 and subtle to moderate in 43. In all 60 cases the patients had suffered from severe congestive circulatory disturbances which (except in 1 case) were due to heart disease. Cardiac hypertrophy was seen in 52 (97%) cases. Of 30 patients listed as cases of coronary artery disease, all presented recent or healed myocardial infarcts (or both) and/or coronary occlusions, while 17 had well-documented histories of hypertension. No correlation between severity of pancreatic changes and type of heart disease was noted, whereas correlation with other parameters of cardiovascular disease and congestive heart disease was rough and inconstant. The frequency of pleural effusion was greater in mild and moderate cases (70% and 41%, resp.), while that of ankle edema was greater in severe cases (75% as compared to 51%). Av. liver wt. and degree of splenomegaly were similar in patients with severe or mild to moderate changes. Thromboembolic complications were highest in cases with severe pancreatic changes. The significance of these findings is discussed.

EXOCRINE PANCREAS

- 7942 EXOCRINE PANCREATIC FUNCTION AFTER PANCREATODUODENECTOMY. (Jap.) Sano, S. (Nagoya U. Sch. Med., Japan). Nagoya Igaku (J. Nagoya Med. Assn.) 88(1): 86-116, 1965.

Exocrine pancreatic function (pancreatic juice obtained by the insertion of a polyethylene tube into the pancreatic duct during pancreaticojejunostomy according to Imanaga) was studied in 10 patients who were subjected to pancreaticoduodenectomy (Imanaga method) for cancer 2 yr. previously. Total pancreatic secretion was normal in 5 long-term survivors following stimulation by pancreozymin-secretin, and various digestion, absorption, vagal stimulation, and D-xylose tests were also normal. An indefinite preservation of normal pancreatic function is suggested with this surgical procedure. Exocrine pancreatic secretion continued in the fasting state, but rhythmical secretion did not always occur. Alcohol and bile stimulated pancreatic secretion much less than expected. Ether and HCl promptly stimulated pancreatic secretion, but the vol. of the secretion showed no correlation with pH. Secretion was immediately increased by ingestion of food, followed by decrease after 1 hr., with return to increased levels after 2-3 hr. The first increase is thought to be of nervous origin, while the second is attributed to stimulation by protein, carbohydrates, and their metabolic products. Fat and its metabolic products stimulated pancreatic secretion much less than expected.

- 7943 VALUE OF THE DOUBLE SECRETIN-PANCREOZYMIN TEST IN THE BIOLOGICAL DIAGNOSIS OF PANCREATIC DISEASE. (Fr.) Plessier, J. (Saint Antoine Hosp., Paris), A. Taschieri, F. Lemonnier, B. Plessier and Vien Lie Em. Acta Gastroent. Belg. 29(2):173-178, 1966.

Pancreatic secretion was studied after i.v. inj. of secretin (1 U/kg) and pancreozymin (3 U/kg) in 143 controls, 66 patients with chronic pancreatitis, and 18 patients with cancer of the pancreas. Significant differences in vol. and lipase (Bondi method) and bicarbonate (Van Slyke method) conc. were observed between controls and pancreatitis patients. The av. vol. of pancreatic secretion at 40 min. after secretin was 74.36 ml in pancreatitis patients as compared to 100 ml in controls. Av. max. bicarbonate conc. after secretin and pancreozymin was 50 and 47.4 mEq, resp., in pancreatitis patients as compared to 96 and 74.4 mEq, resp., in controls. Av. max. lipase conc. after secretin and pancreozymin was 41.5 and 51.6 Bondi U, resp., in pancreatitis patients as compared to 70.5 and 81.6 Bondi U, resp., in controls. No significant difference was seen in av. values of serum and urinary amylase in pancreatitis patients and controls 1.5 hr. after i.v. inj. of secretin. Av. max. conc. of bicarbonate and lipase after secretin or pancreozymin did not differ in cancer patients and patients with chronic pancreatitis. It is concluded that the secretin-pancreozymin test is of value in the detection of pancreatic disease, although concomitant cytological studies and arteriography are necessary to determine with certitude the nature of the pancreatic disease.

- 7944 SERUM KALLIKREINOGEN LEVELS IN POSTOPERATIVE PATIENTS AND IN PATIENTS WITH PANCREATITIS. (E.) Singh, L. M. (Hahnemann Coll. Med., Philadelphia Pa.) and J. M. Howard. Surgery 59(5):837-841, 1966.

Kallikreinogen blood levels were determined (according to Frey *et al.* and Forrell) in normal subjects, in 19 patients with various pancreatic diseases (including acute or chronic pancreatitis and carcinoma of the pancreas), and in 16 postoperative (nonpancreatic) patients. Kallikreinogen levels were reduced (av. normal values = 2.7 Frey U/ml of serum) in patients with acute pancreatitis and in several with chronic pancreatic disease. In others, no consistent correlation between kallikreinogen level and pancreatic amylase or clinical condition could be demonstrated. Of 10 patients who at some time showed no kallikreinogen activity 1 had carcinoma of the pancreas and the others had acute or chronic pancreatitis. The sera of postoperative patients always demonstrated a detectable kallikreinogen activity with levels not significantly different from those of normal controls. The method of assay is relatively crude to permit conclusions based on quantitative data, but should give valid data if interpreted on a semiquantitative or qualitative basis.

CRINE PANCREAS

- 5 PANCREATICODUODENAL CANCER. EXPERIENCE FROM 1951 TO 1960 WITH A LOOK AHEAD AND BEHIND. (E.) Morris, P. J. (Harvard Med. Sch., Boston, Mass.) and G. L. Nardi. Arch. Surg. (Chicago) 92(6):834-837, 1966.
152 patients with pancreaticoduodenal cancer seen in 1951-1960, 38 (25%) underwent pancreaticoduodenectomy, 85 (56%) underwent palliative bypass surgery, and 29% were inoperable or underwent laparotomy only. Of the 38 patients undergoing pancreaticoduodenectomy, 21 survived the procedure and were discharged, and 7 of these patients survived for 5 yr. In the previous decade, 4 of 43 operated patients survived 5 yr., and 2 of these died of disease within 6 yr. The operative mortality rate was high; 12 deaths were attributed to technical errors. Of 121 patients with carcinoma of the head of the pancreas, 26 underwent pancreaticoduodenectomy; 2 of the 15 patients who survived resection were without disease after 10 yr. The 5-yr. survival rate was 13% and the median survival time was 21 mo. By comparison, the median survival time was only 6 mo. in 14 patients who underwent bypass procedures despite their suitability for resection. There were 16 patients with carcinoma of the papilla of Vater; 2 of the 5 who survived resection were alive without recurrence after 8 and 10 yr. By comparison, 1 of 18 patients operated between 1941-1950 survived 5 yr. Eight patients had carcinoma of the common bile duct; 3 underwent resection and 2 survived for 8 and 9 yr. The 5-yr. survival rate in the previous decade was about 33%. Of 7 patients with duodenal carcinoma, 4 underwent resection and 2 survived; 1 died of recurrence after 15 mo., the other was without recurrence after 6 yr. It is concluded that further experience with pancreaticoduodenectomy will improve the survival rates.

Pancreatitis

- 2 THE NATURAL HISTORY AND PROGNOSIS OF ACUTE PANCREATITIS. (E.) Trapnell, J. E. (Frenchay Hosp., Bristol, England). Ann. Roy. Coll. Surg. Eng. 38(5):265-287, 1966.

The records of 347 patients seen between 1950-1961 in Bristol hospitals, and 56 other cases seen by the author, are reviewed. The diagnostic criteria for acute pancreatitis were strict: typical pancreatic lesions at operation or autopsy, and persistent elevation of serum amylase above 1000 Somogyi U/ml. In 324 patients with primary acute pancreatitis, the etiology was gallstones in 180, alcoholism in 2, idiopathic in 129 (5 patients were later diagnosed as cancer of the pancreas or papilla of Vater), and unspecified causes in 9. The mortality rate was 76% (76 patients). Autopsy examination of these patients showed edema with fatty necrosis as the predominant feature of fatal acute pancreatitis in the first 7 days; hemorrhage was less frequent and never confluent. In the second wk., hemorrhagic changes became more marked, but recognizable pancreatic tissue was still present. Most of the patients (57) had died during this early period. Necrosis and autodigestion became the dominant features after 3 wk., and abscesses at 5 wk. more; a review of these "late" fatal cases (19) showed a progressive course in spite of all treatment, together with a lack of recognition of the extent of the disease. Secondary acute pancreatitis was present in 23 patients; the origin was traumatic in 5 patients (all of whom survived) and operative in 18 (all but 2 died). The prognosis of acute pancreatitis was not affected by the etiology (except for traumatic pancreatitis, often fatal, and mumps pancreatitis, which runs a benign course) or the presence of associated diseases (except for pre-existent cardiovascular disease or diabetes mellitus, both of which worsen the prognosis). The mortality rate was increased in very young and (especially) aged patients. The only physical signs of prognostic significance seemed to be staining of the flanks or appearance of a mass in the initial stages, and paralytic ileus at a later stage. Mortality rates after surgery or conservative treatment were the same (23.1% and 26%, resp.). Laboratory tests of prognostic value were serum calcium, fibrinogen, hemoglobin, WBC, and methemalbumin levels. It is concluded that acute pancreatitis, even if recurrent, rarely progresses to chronic pancreatitis.

- 3 CHRONIC PANCREATITIS INDUCED IN RATS BY CATHETERIZATION OF THE COMMON BILE DUCT. (Fr.) Caulin, C. (Bichat Hosp., Paris), F. Potet, M. Dubrasquet, F. Carnot and S. Bonfils. Arch. Mal. Appar. Dig. 55(4):321-326, 1966.

Chronic pancreatitis was induced in 165 Wistar rats (wt. 200-300 g) by catheterization of the common bile duct. The catheter was inserted into the common bile duct for a distance of 1-3.3 cm after duodenotomy and was kept in place by tissue suture alone. The catheter remained in place in very few animals after day 8. Survival was approx. 50% up to day 21. Long term macroscopic studies (1-3 mo.) revealed progressive dilatation of the common bile duct and increase in periductal fibrosis; early studies showed practically no change in the diameter of the common bile duct, indicating that dilatation appears only after 8 days. Microscopic studies (93 animals) revealed acute reactive phenomena (congestion, edema, steatonecrosis) in a majority of rats at days 2 and 4, and to a lesser degree at day 8 (10-20%). Inter- and intralobular fibrosis appeared by day 2 in 50-70% of animals. Subacute changes (vacuolization, differentiation) occurred in 50-70% of animals. Long-term studies (1-3 mo.) revealed the persistence of acute phenomena in 40-60%; fibrosis became more organized and spread to the whole pancreas in 30% of the rats after 1 mo.; massive regression of glandular parenchyma, replaced by diffuse lipofibrosis or sclerolipomatosis, was observed frequently. No liver damage was seen, except for sclerotic changes with dilatation of bile canaliculi in 5-10% of animals. Results indicate a specific response of the pancreas, probably by nerve pathways, to the irritation caused by catheterization of the common bile duct.

- 4 MODIFICATIONS IN THE FLOW AND COMPOSITION OF THORACIC DUCT LYMPH INDUCED BY EXPERIMENTAL PANCREATITIS IN DOGS. (Fr.) Sim, D. N. (Northwestern U. Sch. Med., Chicago), A. Duprez and M. C. Anderson. Acta Gastroent. Belg. 29(2):235-247, 1966.

The flow and composition of thoracic duct lymph was studied in mongrel dogs subjected to simple cannulation of the thoracic duct (Group 1; 4 dogs); cannulation and acute pancreatitis induced by ligation of the superior pancreatic vein and accessory pancreatic ducts and inj. of 83.33 U of lyophilized trypsin (Group 2; 5 dogs); cannulation, acute pancreatitis, and perfusion with dextran or fresh plasma (Group 3; 7 dogs); cannulation, acute pancreatitis, and postoperative inj. of Cr⁵¹-labeled RBC (Group 4; 2 dogs). Dogs of Group 1 were able to maintain a flow of 31 ml/hr. for 24 hr.; lymphatic levels of lipase (Cherry-Crandall U/100 ml) and amylase (Somogyi U/ml) ranged from 1.2-5.8 and 1,100-1,600, resp. In dogs of Group 2, an immediate increase in the vol. of lymph was followed by a decrease after 3-5 hr. lymph changed from opalescent to bloody; lymphatic amylase and lipase levels were increased 100-1,000% with respect to controls; all animals died from hemorrhagic pancreatitis within 10-21 hr. In animals of Group 3, 4 of 7 survived 48 hr.; parenteral fluid replacement failed to increase thoracic duct flow, which was similar to that observed in animals of Group 2, although some beneficial effect on the pancreas of surviving animals was seen; lymphatic lipase and amylase levels were markedly increased. In animals of Group 4, lymphatic radioactivity was increased, reaching a max. after 7 hr.; mesenteric lymph nodes showed no significant increase in radioactivity; venous radioisotope uptake at the time of death was 40% greater than that observed in controls. It is concluded that RBC enter the lymphatic system during experimental hemorrhagic pancreatitis from the interlobular and intercellular spaces, and form aggregates which partially or totally obstruct drainage through the local lymphatic circulation. Lymphatic absorption of extravasated fluid is decreased and the hypovolemic state enhanced.

7975

KULCHITSKY-MASSON CELLS AND SUBACUTE EPISODES OF CHRONIC PANCREATITIS. A STUDY OF THE INDUCED BLOOD SEROTONIN TEST IN 6 CASES OF LITHOGENOUS PANCREATITIS TREATED SURGICALLY. (Fr.) Geffroy, Y. (Charles-Nicolle Hosp., Rouen, France), J. Bourreille, J. Fablet and G. Cayron. Arch. Mal. Appar. Dig. 55(4):289-296, 1966.

Induced blood serotonin curves (method described by the authors in a previous report) were studied in 6 male surgical patients (age 30-50 yr.) with chronic pancreatitis established by clinical and operative findings. Tests were performed after surgery in 5 and before and after surgery in 1. Curves were abnormal in all patients. In 2 patients subjected to biliary-digestive tract anastomosis or cystoanastomosis, curves were similar to those observed earlier in patients with lithogenous pancreatitis of less than 4-yr. duration; duration of pancreatitis was 15 mo. and 5 yr., resp., in these patients. In 1 patient treated by gastroenterostomy, curves were similar to those observed earlier in patients subjected to gastroenterostomy or gastrectomy and showing poor adaptation to their postoperative state; increased serotonin response in these patients suggested an irritable effect on Kulchitsky cells and a deleterious effect on the course of the pancreatitis. In 3 patients treated by left pancreatectomy with pancreaticojejunostomy, blood serotonin levels at fasting were higher than normal, as was observed earlier in patients with small intestine inflammation; in 2 cases, the abnormally high serotonin level did not prevent a positive response to digestive tract stimulation. Results seem to indicate hyperactivity of Kulchitsky cells in pancreatitis.

7976

HEPATIC MORPHOLOGY AND FUNCTION. ALTERATIONS ASSOCIATED WITH ACUTE PANCREATITIS. (E.) Anderson, M. C. (Northwestern Sch. Med., Chicago, Ill.). Arch. Surg. (Chicago) 92(5):664-671, 1966.

The effect of pancreatic inflammation on liver morphology and function was studied in 5 groups of dogs (10/group) following ligation of the smaller pancreatic duct and: (1) ligation of larger pancreatic duct; (2) ligation of larger pancreatic duct plus 2 U/kg secretin i.v. and 5 mg bethanechol s.c.; (3) inj. of 10-12 ml trypsin soln., 10,000 U/ml into the larger pancreatic duct; (4) intraductal trypsin plus ligation of superior pancreatic vein; (5) intraductal inj. of 10-12 ml enzyme digested autologous whole blood. Autopsies were performed as soon as possible after death and survivors were sacrificed at 72 hr. The findings were: (1) all animals survived 72 hr. with little change in hepatic cells and mild edema of intralobular

spaces; (2) all animals survived 72 hr. and liver cords were separated with congestion of sinusoids of pericentral area; (3) 8 of 10 dogs survived 72 hr. with extensive pancreatic damage, shrunken liver cords and distended sinusoids; (4) 4 of 10 dogs lived 72 hr. with extreme pancreatic necrosis and hepatic cell degeneration; (5) 2 of 10 dogs lived 24 hr. with severe necrotizing pancreatitis and hepatic cell degenerative changes with focal necrosis. Liver function studies in Groups I to IV indicated that as pancreatitis became more severe, liver function (as measured by thymol turbidity, alkaline phosphatase, serum glutamic-pyruvic transaminase and serum glutamic-oxalacetic transaminase) became more abnormal. It was concluded that, as pancreatitis became more severe, intrahepatic circulatory stasis occurred and was associated with hepatic parenchymal damage.

- 9777 SERUM LIPASE DETERMINATION IN ACUTE PANCREATITIS. CLINICAL APPRAISAL OF A NEW METHOD. (E.) Patt, H. H. (Sinai Hosp., Baltimore, Md.), S. P. Kramer, G. Woel, D. Zeitung and A. M. Seligman. Arch. Surg. (Chicago) 92(5):718-723, 1966.

The clinical value of a new colorimetric serum lipase determination (according to Kramer) was assessed in 304 patients with abdominal pain. Among 31 patients with acute pancreatitis proved at laparotomy or autopsy, the test was more sensitive than serum amylase; serum lipase was elevated in 23 patients (74%) at some time during their hospital stay; serum lipase was more frequently positive in the early stages of the disease and it paralleled the clinical course more closely, frequently remaining positive 1-16 days after serum amylase had returned to normal. Among 169 patients with no pancreatitis demonstrable at laparotomy or autopsy, serum lipase test was positive in 31 patients at some time in their clinical course, while serum amylase was elevated in 18. However, in 28 of these 31 patients, there were reasonable explanations for an elevated serum lipase and their treatment was not adversely affected by the positive test. On the contrary, many patients with biliary tract disease and associated pancreatitis were benefited by improved timing of surgery. Of the patients with unexplained elevations of serum amylase or serum lipase, 3 had bowel obstruction, 1 had hemopneumothorax, and 1 had acute appendicitis.

- 9778 PERITONEAL LAVAGE IN EXPERIMENTAL PANCREATITIS IN DOGS. (E.) Rodgers, R. E. (Marquette U. Sch. Med., Milwaukee, Wis.) and L. C. Carey. Am. J. Surg. 111(6):792-794, 1966.

Pancreatitis was induced in adult mongrel dogs by ligation of the lesser pancreatic duct, and peritoneal lavage with 1,000 ml of Hartman's soln. was performed through the sump drain at 2, 4, and 6 hr. after pancreatitis. Control animals were not subjected to peritoneal lavage. Death occurred in 58% of experimental animals and 88% of control animals; intussusception occurred in 33% of all dogs studied, resulting in their being discarded from the study. Dogs subjected to peritoneal lavage usually had a much better general appearance 24 hr. after pancreatitis than controls. No difference was observed in blood or chemistry determinations in experimental or control groups. The peritoneal fluid in experimental pancreatitis contains an albumin-like substance in greater conc. than that found in the serum. The role of this protein fraction in the toxicity of pancreatitis is unknown.

- 9779 CONTRIBUTION OF SELECTIVE ANGIOGRAPHY OF THE CELIAC TRIAD TO THE DIAGNOSIS OF CHRONIC PANCREATITIS. (It.) Cavassini, G. B. (U. Bologna, Italy), S. Moretti, G. Fontana and E. Manzini. Minerva Gastroent. 11(3):128-131, 1965.

After describing a technic for the selective angiography of the celiac triad, the authors report some of the findings observed in various patients with chronic pancreatitis. In the arterial phase, the arteries of the head of the pancreas were highly visualized with abundant anastomoses and marked tortuosity of the intrapancreatic vessels. The capillary phase revealed a non-uniform opacity (frequently of a granular nature) along with marked enlargement of the head. It is concluded that the chronic inflammatory process causes sclerosis in various zones of the pancreas which in turn is responsible for disorganization of the normal vascular structure.

EXOCRINE PANCREAS

Pancreatitis

- 7980 USE OF CARBONIC ANHYDRASE INHIBITOR IN THE TREATMENT OF PANCREATITIS. (E.) Anderson, M. C. (Northwestern U. Sch. Med., Chicago, Ill.) and M. K. Copass. *Am. J. Dig. Dis.* 11(5):367-376, 1966.

Acetazolamide was admin. to 26 patients (14 women and 12 men; age 28-63 yr.) with acute edematous pancreatitis established by clinical, laboratory, and operative findings; 17 had experienced previous attacks; 1 patient developed pancreatic necrosis; 12 patients had chronic alcoholism and 13 had chronic biliary tract disease. Treatment was usually begun with a rapid infusion of 500 ml of dextrose soln. containing 500 mg of acetazolamide; subsequently, 1-2 g of the drug were added to the fluids every 24 hr. Of 17 patients treated with acetazolamide alone or in combination with meperidine hydrochloride as the only immediate treatment, or in whom the drug was used subsequent to other therapy (including nasogastric suction, anticholinergic drugs, and narcotics), prompt improvement in the clinical course was observed. In 6 patients, acetazolamide treatment was begun immediately along with other accepted forms of therapy; pain, nausea, and epigastric fullness were relieved within a few hr. and did not recur, while abdominal tenderness usually disappeared within 72 hr. In 3 patients, acetazolamide was admin. as part of the patient's treatment, but had no demonstrable effect upon the course of the disease. No serious side effects were encountered with the dose schedule used in this study. No control group was included.

- 7981 ACHLORHYDRIA ASSOCIATED WITH CHRONIC DISEASE OF THE EXOCRINE PANCREAS. (E.) MacLaren, I. F. (Hahnemann Coll. Med., Philadelphia, Pa.), J. M. Howard and O. Serlin. *Surgery* 59(5):676-680, 1966.

Gastric secretion of acid, utilizing the 12-hr. overnight gastric collection followed by the augmented histamine test, was studied in 34 patients with chronic pancreatic disease (28 chronic pancreatitis and 6 advanced carcinoma). During the 12-hr. collection, 30 patients produced less than 5 mEq of free HCl (normal 15-30 mEq) while no free HCl was obtained from 22 patients. Within the hr. following augmented histamine stimulation, 25 patients produced less than 5 mEq of free HCl (normal 10-30 mEq), while no free HCl was obtained from 13 patients. In 3 patients who had undergone prior surgery for duodenal ulcer, gastric acid output both during 12-hr. collection and after augmented histamine stimulation was very low, ^{131} I-labeled triolein uptake was normal, and overt steatorrhea was not present. Nine patients had overt clinical steatorrhea, and these, as well as 6 others, demonstrated impaired ^{131} I-labeled triolein uptake; of these, 10 had no free HCl in the 12-hr. overnight collection and 6 produced none after augmented histamine stimulation.

- 7982 PANCREATITIS AND HYPERLIPEMIA: A STUDY OF SERUM LIPID ALTERATIONS IN 25 PATIENTS WITH ACUTE PANCREATITIS. (E.) Greenberger, N. J. (Ohio State U. Sch. Med., Columbus), F. T. Hatch, G. D. Drummey and K. J. Isselbacher. *Medicine (Balt.)* 45(2):161-174, 1966.

Hyperlipemia associated with abdominal pain and fever was seen in 3 of 25 patients with acute pancreatitis, but these 3 patients did not show serum amylase or lipase levels in the range considered diagnostic for acute pancreatitis. Two of them were alcoholics (as were 9 patients in the group without hyperlipemia); in 1 of these, acute pancreatitis began immediately after excessive drinking on 2 occasions. In all 3 cases, hypertriglyceridemia with lactescent serum was noted during the acute attacks; serum triglycerides decreased (markedly in 2 cases) after the end of the acute episode, but did not fall to normal levels. Other studies in these patients demonstrated persistently impaired serum postheparin lipolytic activity, abnormal lipoprotein electrophoresis patterns and fat tolerance tests, prolonged chylomicronemia after fat loading, and minimal to moderate triglyceridemia when symptom-free. It is suggested that this triglyceridemia represented a latent defect in lipid metabolism, aggravated by the development of acute pancreatitis, rather than any of the recognized forms of primary or essential hyperlipemia. Serum lipids were normal at all times in the other 22 patients.

- 7983 THE ROLE OF INTRADUODENAL HYPERTENSION IN THE DEVELOPMENT OF PANCREATITIS (Rus.) Toskin, K. D. (Crimean Med. Inst., Simferopol, USSR), V. A.

Protsenko, Iu. N. Kolesnikov and L. B. Rozinskii. Pat. Fiziol. Eksp. Ter. 10(1):10-14, 1966.

The influence of the degree and duration of elevated intraduodenal pressure on the development and progression of experimentally induced acute and chronic relapsing pancreatitis was investigated in 28 dogs. Three hours after occlusion of the externalized duodenal stump in one group of dogs, acute pancreatic edema developed, with a microscopic picture of polyemic interstitial tissue and slight diapedesis of RBC. Changes in serum pancreatic enzyme activities were not always conspicuous at this stage, but with the further development of pathologic changes in the pancreas (including serous inflammation, leukocytic infiltration, and incipient necrosis after 9 hr.), there was a significant and persistent increase in serum amylase and lipase activity. After 24 hr., distinct necrobiotic and necrotic changes were observable in the pancreatic parenchyma. In 2 dogs, chronic relapsing pancreatitis was simulated by clamping the duodenum for 6 hr. at a time on 3 occasions over a period of 3-4 mo. At autopsy, the pancreas was enlarged and of cartilage-like consistency, with a microscopic picture of pronounced fibrosis. During the artificially induced "relapses", there was a sharp rise in serum pancreatic enzyme activity; in the intervals between them, this was within normal limits. When duodenal occlusion and stimulation of pancreatic function with 1% pilocarpine were combined, the result was acute hemorrhagic necrosis, the pathologic changes progressing much more rapidly than with occlusion alone. Partial duodenal occlusion for 24 hr. combined with 3 applications of pilocarpine at 3-hr. intervals left the dogs in satisfactory condition, and although the pancreas was hyperemic at autopsy, its histologic structure was intact. With this experimental design, serum amylase was sharply increased in the first 6 hr., essentially normal at 24 hr.; there was no appreciable change in serum lipase activity. Increased intraduodenal pressure resulting from paresis of the sphincter of Oddi would therefore seem to play a decisive role in the pathogenesis of pancreatitis, and heightened pancreatic function accelerates and exacerbates the disease.

184 ACUTE PANCREATITIS FROM VITAMIN-D POISONING IN A PATIENT WITH PARATHYROID DEFICIENCY. (E.) Leeson, P. M. (Manor Hosp., Derby, England) and P. Fourman. Lancet 1(7448):1185-1186, 1966.

A woman with hypoparathyroidism immediately after a second thyroidectomy for thyrotoxicosis developed generalized tetany prior to discharge from the hospital, complicated by laryngospasm and severely decreased serum calcium resistant to treatment with calcium + dihydrotachysterol or calcium + vitamin D₂. There were two epileptic episodes during approx. one-half yr. of observation. Substitution of vitamin D₃ for vitamin D₂, accompanied by a 400% increase of the calcium supplement, was followed by a relatively slow, steady rise of serum calcium to maximal normal levels; then by an abrupt rise to extremely high levels, decrease of serum magnesium to extremely low levels, drowsiness, confusion, grand mal and finally, intractable, generalized abdominal pain. Severe hemorrhagic pancreatitis, attributed to the rise of serum calcium, was demonstrated at surgery. The epilepsy, in turn, was attributed to the fall in serum magnesium. It is concluded that pancreatitis secondary to hyperparathyroidism may be due to hypercalcemia, rather than to any direct effect of the parathyroid hormone on the pancreas.

185 SERUM ENZYME CHANGES IN EXPERIMENTAL PANCREATITIS IN THE DOG. (Ger.) Grözinger, K. H. (U. Heidelberg, Germany), M. Wanke, K. Hochberg, H. W. Schüller, S. I. Walter, P. Welsh and D. Farnusch. Zschr. Ges. Exp. Med. 140(2):136-148, 1966.

Acute hemorrhagic pancreatitis was induced in dogs by intrapancreatic infusion of sodium taurocholate and trypsin. Serum determinations of alpha-amylase and leucine aminopeptidase showed increases at 6 and 12 hr. (when the dogs were sacrificed) in post, but not at a level of statistical significance. Glutamic-oxaloacetic transaminase was significantly increased at both times; as were the 12-hr. but not the 6-hr. determinations of glutamic-pyruvic transaminase, lactic dehydrogenase and alkaline phosphatase. The increases reported appeared to result from complex lesions of the heart muscle and hepatic tissue, rather than from pancreatic damage as such.

- 7986 PANCREATITIS AND EFFUSIONS. (Fr.) Moreaux, J. (Bichat Hosp., Paris), J. P. Clot, M. Mercadier and J. Hepp. Ann. Chir. 20(5-6):413-423, 1966. Nine cases of massive, recurrent effusion secondary to pancreatitis are reported. The pancreatitis was acute in 2 cases; chronic and calcifying in 17. The immediate source of effusion was found to be a localized area of necrosis and rupture of a pseudocyst in either the caudal or the cephalic region of the pancreatic body. Seven of the patients had ascites; 2 had pleural effusions; 1 had both. Hemorrhagic effusion occurred in only 1 case, chylous effusion in only 1. Both were in patient with ascites. Serohemorrhagic effusions were seen in 4 patients, serofibrinous effusions in 3. In all cases, amylase activity in the fluid was markedly increased, ranging from 450-102,500 Somogyi Units. It is suggested that such a marked increase of amylase activity in a pleural or peritoneal effusion is strongly suggestive of pancreatic origin.

LIVER AND BILIARY TRACT
GENERAL

- 8010 GLUCURONIC ACID CONJUGATION OF 4-¹⁴C-CORTISOL METABOLITES IN ICTERUS INTERMITTENS JUVENILIS. (Nor.) Abrahamsen, A. M. (U. Bergen, Norway) and K. F. Støa. Nord. Med. 75(7):179-181, 1966.

Glucuronic acid conjugation was studied in a 16-year-old boy with Gilbert's disease (icterus intermittens juveniles) to whom 4-C¹⁴-cortisol was admin. i.v. Urine samples collected over 24 hr. contained 48.5% free low-polar cortisol metabolites as compared to a mean of 5.1% in normal adults. Although the reduction of high-polar metabolites in the patient was not significant, urine low-polar and high-polar glucuronide levels were 37 and 6%, resp., as compared to 54.3 and 10.9%, resp., in controls. The ratio between total glucuronides and total free metabolites was 6.2 in controls and 0.85 in the patient. Results indicate that the hyperbilirubinemia in Gilbert's disease is caused by reduced conjugation with glucuronic acid.

- 8011 EXPERIMENTAL BILIRUBIN ENCEPHALOPATHY. THE MODE OF ENTRY OF BILIRUBIN-BILIRUBIN-¹⁴C INTO THE CENTRAL NERVOUS SYSTEM. (E.) Diamond, I. (U. Chicago, Ill.) and R. Schmid. J. Clin. Invest. 45(5):678-689, 1966.

C¹⁴-Bilirubin either bound to human albumin or dissolved in aqueous taurocholate soln. or guinea pig serum was infused (i.v.) into newborn guinea pigs or adult Gunn rats. Admin. of the unbound C¹⁴-bilirubin produced lower serum conc. and higher brain levels of radioactivity than when the pigment was given bound to human albumin; the brain to serum ratio was 5:1 in rats and 6:1 in guinea pigs. The bilirubin deposited in the brain by infusion with unbound pigment was returned to the serum in part by inj. of human albumin; sodium salicylate infusion shifted bilirubin from the plasma to the brain; and production of metabolic acidosis (by 0.5 N HCl infusion) doubled brain bilirubin conc. Infusion of bilirubin in guinea pig serum, 100 µg/g body wt./hr., into newborn guinea pigs produced severe neurological disturbances in 11 of 30 and death in 7 of 30 in 24 hr. while infusion of bound bilirubin did not produce neurological damage in 15 guinea pigs although their serum bilirubin conc. was significantly higher. The survival rate of animals given unbound bilirubin was increased by treatment with human serum albumin. The results indicated that only unbound bilirubin can cross the blood-brain barrier and provided experimental support for the proposed use of albumin in prevention and treatment of bilirubin encephalopathy in neonatal hyperbilirubinemia.

- 8012 DIAGNOSTIC VALUE OF PERCUTANEOUS LIVER BIOPSY IN JAUNDICE OCCURRING DURING PREGNANCY. (Ger.) Thiele, P. (Carl Gustav Carus Acad. Med., Dresden, Germany) and W. D. Sengebusch. Zschr. Ges. Inn. Med. 21(8):68-70, 1966.

In a group of jaundiced, pregnant women, only liver biopsy was successful in differential diagnosis as between the idiopathic jaundice of pregnancy and the other, common forms of this disorder. In the light of percutaneous liver biopsy findings it was determined that approx. 70% of the group suffered from the idiopathic jaundice of pregnancy; 17%, from acute infectious hepatitis; 14%, from chronic hepatitis. The author comments that Menghini's method of percutaneous liver biopsy can usually be carried out without difficulty, even in the latter stages of pregnancy.

- 8013 THE LIVER IN PATIENTS WITH HEPATIC PORPHYRIA, WITH PARTICULAR CONSIDERATION OF PORPHYRIA CUTANEA TARDA. (Ger.) Creutzfeldt, W. (U. Göttingen, Germany), K. Beck, R. Clotten and L. Bianchi. Acta Hepatosplen. (Stuttgart) 13(2):65-83, 1966.

Among 23 patients with acute, intermittent hepatic porphyria, there were no cases of hepatic cirrhosis or hepatomegaly. Some increase of serum glutamic pyruvic transaminase was observed in all patients. A significant increase of sulfobromophthalein sodium was seen in approx. 3 of 4; of serum gamma-globulins in approx. 1 of 3. Increases of serum bilirubin or serum iron were seen less frequently. Liver biopsies showed only a few instances of (minimal) morphologic changes. Among 31 cases of porphyria cutanea tarda, laboratory findings were essentially consonant with the above, but 81% of the group had developed hepatomegaly, approx. 1 of 3

LIVER AND BILIARY TRACT

ad hepatic cirrhosis, approx. 3 of 5 had a moderate degree of siderosis, and approx. 10 showed either severe siderosis, fibrosis, chronic hepatitis and/or an advanced degree of fatty degeneration. Determinations of hepatic porphyrins in 4 cases of acute porphyria and 11 of porphyria cutanea tarda showed an increase of protoporphyrins to approx. 10 and 100 times normal levels, resp. Increases of coproporphyrins were not statistically significant. The authors conclude that porphyria cutanea tarda may result from a latent enzymatic defect which becomes manifest following damage from an exogenous agent or following liver disease.

- 014 CHRONIC LIVER DISEASE AND RENAL FUNCTION. (Ger.) Schmidt, H.-G. (U. Giessen, Germany) and K. Schultis. Acta Hepatosplen. (Stuttgart) 13(2): 105-110, 1966.

Inulin and para-aminohippuric acid (I) clearance values, together with the dilution capacity of the distal nephron, were estimated for two groups of patients: one, with chronic hepatitis tending toward hepatic cirrhosis but without any tendency toward edema; the other, with established cirrhosis of the liver and a tendency toward edema which could be controlled only under hospital conditions. None of the subjects was jaundiced. All three values were significantly decreased among the cirrhotic patients, with I-clearance values decreased to a significantly greater degree than those for inulin clearance. The authors conclude that the impaired renal function frequently observed in chronic liver disease is a product of disturbance of intrarenal hemodynamics.

- 015 CLINICAL INVESTIGATIONS OF THE POSSIBLE CHOLESTATIC ACTION OF 1 α -METHYL-5 α -ANDROSTAN-17 β -OL-3-ONE (MESTEROLONE). (Ger.) Schnack, H. (U. Vienna, Austria) and F. Wewalka. Arzneimittelforschung 16(4):471-472, 1966.

In a short-term study, 16 patients with chronic liver diseases (cirrhosis, fatty liver, postinfectious hepatomegaly, recurrent hepatitis, porphyria cutanea tarda, cholangitis, enteritis) were treated with Mesterolone at 20 or 60 mg/day (in 9 and 7 patients, resp.) for 1-4 wk. Eight other patients with chronic liver diseases received the agent (20 mg/day) for up to 6 mo. There were no significant changes in the various biochemical indices of cholestasis (sulfobromophthalein retention, serum bilirubin, glutamic-oxalacetic transaminase, or leucine aminopeptidase) with either short-term or long-term admin. of this anabolic agent. The possibility that this agent might induce intrahepatic cholestasis in susceptible women during pregnancy was not ruled out, however. Mesterolone therefore differs from the structurally similar anabolic agents norethandrolone and methyltestosterone in its lack of cholestatic activity.

- 016 TOLERANCE OF 1 α -METHYL-5 α -ANDROSTAN-17 β -OL-3-ONE (MESTEROLONE) BY THE LIVER. (Ger.) Pohle, H. D. (Rudolf Virchow Hosp., Berlin). Arzneimittelforschung 16(4):473-474, 1966.

Mesterolone (an anabolic agent) was admin. to 6 women and 16 men with normal liver function. In 13 patients given the therapeutically effective dose (30 mg/day) for 1-4 wk., there were no changes in serum transaminase or sulfobromophthalein retention values. Another patient with an encephalitic syndrome with fever of unknown etiology showed some disturbances in liver function during treatment; but since liver function studies had not been performed before treatment was begun, it was not known whether these changes resulted from admin. of mesterolone. When the dose was increased to 60 mg/day in 8 other patients, a slight increase in serum transaminases (in 4 patients) and a retardation of sulfobromophthalein excretion (in 3 of 7 patients tested) were seen after 20-50 days of treatment; these changes were minimal.

- 017 POSSIBLE RELATIONSHIP OF OPTIC NEURITIS, WILSON'S DISEASE, AND DL-PENICILLAMINE THERAPY. (E.) Goldstein, N. P. (Mayo Clin., Rochester, Minn.), R. W. Hollenhorst, R. V. Randall and J. B. Gross. J.A.M.A. 196(8):734-735, 1966.

A man with Wilson's disease failed to respond to DL-penicillamine (1; total 750 mg/day), but the clinical symptoms regressed when this dosage was doubled. Other

LIVER AND BILIARY TRACT

treatment included vitamin K₅, a multivitamin preparation containing pyridoxine (approx. dose 2.5-5.0 mg/day), carbocrylamine resin, and a low copper diet. After 2 yr. of treatment, signs of optic neuritis developed. The dosage of I was reduced to its initial level and carbocrylamine resin was stopped, but the vitamin and diet therapy was continued; after about 1.5 yr. the visual acuity had returned to normal and the optic signs regressed. It is suggested that the optic neuritis resulted from some cause other than pyridoxine antagonism due to I. This is the second reported case of optic neuritis during I therapy for Wilson's disease.

- 8018 AN AUTOPSIED CASE OF A VARIETY OF "HEPATOCEREBRAL DISEASE". (E.) Asao, H. (Wakayama Coll. Med., Japan) and Y. Higashi. Wakayama Med. Rep. 10(1):37-48, 1965.

Autopsy findings of a 31-year-old man with slightly disturbed liver function, repeated episodes of disturbed consciousness, mental and visual disturbances, and other neurological changes of 5-yr. duration are described. The patient's clinical symptoms and the neuropathologic findings at autopsy were intermediate between the Inose type and the pseudoulegyria type of hepatocerebral degeneration; the chief difference was the presence of hepatitis in this patient, instead of cirrhosis. Intoxication due to a metabolic disturbance and/or liver disease was tentatively identified as the cause of the neurological changes. No copper or iron was demonstrated histochemically in brain sections.

- 8019 DIAGNOSTIC PROBLEMS OF PYOGENIC HEPATIC ABSCESS. (E.) Berke, J. (Jersey City Med. Ctr., N. J.) and C. Pecora. Am. J. Surg. 111(5):678-682, 1966.

Liver abscesses (involving the right lobe in all cases, with extension to the left lobe in 2) were correctly diagnosed preoperatively in 7 of 10 patients, but the morbidity rate was high and 5 patients died. Causes of this failure to improve morbidity and mortality included delayed diagnosis, faulty culture techniques, and faulty surgical approaches to the abscess cavity. The precipitating cause was appendectomy in 3 patients, acute cholecystitis with cholelithiasis in 2, postabort septicemia in 1, fever of undetermined origin in 1, possible amebiasis in 1, and possible respiratory infection of undetermined origin in 2. Liver abscesses should be considered in all patients with fever of undetermined origin and liver scans performed in all such patients; in this group, there were 3 positive and 3 equivocal scans. Other recommended measures include blood cultures before antibiotic therapy is begun, the use of proper techniques (especially aerobic and anaerobic plating methods) in obtaining liver abscess cultures, X-ray examination of the upper abdomen, hepatic artery catheterization (both diagnostically and to deliver antibiotics to the abscess), proper localization of the incision to expose the abscess, and adequate drainage of the abscess.

- 8020 HEPATIC DYSFUNCTION IN THE CONGENITAL RUBELLA SYNDROME. (E.) Monif, F. R. G. (NIH, Bethesda, Md.), R. Asofsky and J. L. Sever. Brit. Med. J. 1(5495):1086-1088, 1966.

Congenital rubella syndrome was diagnosed in 6 infants after virus isolation from either throat or urine specimens. In addition to the classical stigmata of the rubella syndrome, jaundice was noted within the first 24 hr. in 3 patients, and in all cases within 48 hr. Livers were palpable 3-5 cm; hepatosplenomegaly persisted during the period of hepatic dysfunction. Clay colored stools were observed in 2 patients. While biochemical changes were primarily related to elevations of indirect bilirubin, abnormally high transaminase levels were observed in 2 patients and a reversal of the albumin/globulin ratio late in the course of the disease in 1. Liver biopsy of 1 patient and necropsy liver specimens of 2 other patients, when studied by histological and virus isolation techniques, revealed a correlation between hepatic derangement and recovery of virus. One of the cases at necropsy had histological changes suggestive of early cirrhosis. The recovery of rubella virus from these livers favors the hypothesis that this is a hepatitis of viral origin.

LIVER AND BILIARY TRACT

- 021 REPAIR OF HIGH POSTOPERATIVE STRICTURES OF THE HEPATIC DUCT. A MODIFICATION OF HEPATICOJEJUNOSTOMY. (E.) Seiro, V. (U. Helsinki, Finland) and J. Hästbacka. Acta Chir. Scand. 131(4):343-351, 1966.

The authors describe a modified method of hepaticojejunostomy with a T-tube. This method was applied to 7 patients (6 women and 1 man; age 35-63 yr.) with high hepatic duct stricture resulting from biliary duct lesions during cholecystectomy. The av. time before hepaticojejunostomy with a T-tube was 14.6 mo.; 1 or more prior attempts at reconstruction had been made in 6 patients. No re-stenosis occurred when the T-tube was removed after 1 yr. In 2 patients in whom mucosa-to-mucosa anastomosis was not possible, survivals of 3 and 2.5 yr., resp., were observed; 1 patient has had several episodes of distress but no jaundice, and liver function is almost normal. Two other patients survived for 8 and 5 yr., resp. The only recurrence of stricture occurred in 1 patient when the T-tube was removed after 1 mo.; upon re-insertion of the tube and removal after 1 yr., excellent results were observed for 4 yr. One patient responded well for 15 mo., then died from gastrointestinal hemorrhage; no autopsy was performed. Another patient died of progressive biliary cirrhosis after 1.5 yr., despite marked reduction of jaundice. It is concluded that re-stenosis in strictures of the hepatic duct may best be prevented by the use of an indwelling tube left in the anastomosis at least 1 yr.

- 022 RADIOISOTOPE PHOTOSCAN OF LIVER IN DIFFERENTIAL DIAGNOSIS OF UPPER ABDOMINAL DISEASE: REVIEW OF 232 CASES. (E.) Shingleton, W. W. (Duke U. Med. Ctr., Durham, N. C.), L. A. Taylor and F. J. Pircher. Ann. Surg. 163(5):685-691, 1966.

Hepatic scintillation scans were reviewed in 232 patients, and confirmation of the presence or absence of hepatic or perihepatic disease by biopsy, laparotomy, or autopsy was possible in 150 of these patients. The accuracy of diagnosis of presence or absence of hepatic or perihepatic disease was 90%; 10 false negative and 4 false positive results were observed. Confirmed diffuse liver diseases (51 patients) associated with abnormal scans included cirrhosis (28), jaundice-biliary obstruction (2), hepatitis (6), fatty infiltration (3), glycogen storage disease (3), leukemia (2), tuberculosis (1), and sarcoid (1); confirmed focal liver diseases (46) included metastatic tumor (37), primary tumor (3), liver abscess (2), hemangioma (2), polycystic liver (1), and solitary cyst (1); diseases causing liver displacement (13) included subdiaphragmatic abscess (8), pulmonary disease (3), and extrahepatic mass (2). Various technics and radiological procedures are reviewed.

- 023 USE OF ISOLATED PERFUSED CADAVERIC LIVER IN THE MANAGEMENT OF HEPATIC FAILURE. (E.) Sen, P. K. (Seth G. S. Coll. Med., Bombay, India), R. A. Bhalerao, G. P. Parulkar, A. B. Samsi, B. K. Shah and S. G. Kinare. Surgery 59(5):774-781, 1966.

After encouraging results obtained in the laboratory, isolated perfused cadaveric liver was used in the management of 4 patients with hepatic coma resulting from severe cholangitis, cirrhosis with portosystemic encephalopathy, cirrhosis with acute hepatocellular failure, and acute hepatocellular failure, resp. The apparatus, preparation of donor and recipient, and technic of perfusion are described. Since the 4 cases had reached a desperate state, clinical improvement was temporary but definitely observed, while biochemical improvement was significant and encouraging. There were no survivors and survival was not prolonged. One of the difficulties encountered was proper maintenance of liver temperature. Extended trial of the method is suggested for selected cases of hepatic coma. Since submission of this report, a fifth patient in deep hepatic coma following emergency portacaval shunt is successfully undergone perfusion with clinical recovery.

- 024 HEPATIC FLOW IN DIABETES MELLITUS. APPLICATION OF THE SULFOBROMOPHTHALEIN METHOD FOLLOWING ADMINISTRATION IN SMALL DOSES TO PATIENTS WITHOUT SIGNS OF IMPAIRED LIVER FUNCTION. (It.) Giangrandi, E. (U. Turin, Italy), P. F. Martini, G. P. Molino, A. Cravario and A. Vitelli. Minerva Gastroent. 11(4):177-183, 1965.

Hepatic blood flow was measured after i.v. admin. of sulfobromophthalein (5% soln.)

LIVER AND BILIARY TRACT

in 27 patients (15 women and 12 men; age 14-77 yr.) with diabetes of 1-25 yr. duration but no signs of impaired liver function. Hepatic blood flow was decreased (less than 1,174 ml/min.) in 15 patients, at the lower limit of normality in 2, and normal (1,174 ml/min.) in 10. Reduced hepatic blood flow was observed in 7 of patients with severe diabetes, in patients with diabetes of more than 3 yr. duration, and in those with regional or generalized vascular alterations. No correlation was observed between reduced hepatic blood flow and age. Normal response to liver function tests did not exclude the possibility of reduced hepatic blood flow.

- 8025 HUMAN HEPATIC MICROBODIES WITH CRYSTALLOID CORES. (E.) Biempica, L. (Albert Einstein Coll. Med., New York, N. Y.). J. Cell Biol. 29(2):383-386, 1966.

Crystalloid-containing microbodies were found in human liver biopsy specimens obtained from a 27-year-old male with idiopathic recurrent cholestatic jaundice, diabetes mellitus, and thalassemia minor. In the first biopsy specimen taken at surgery when the patient was jaundiced, the parenchyma was strikingly abnormal and the microbodies dispersed throughout the cytoplasm displayed a homogeneous matrix without evident nucleoids. The second biopsy specimen, taken during the anicteric phase, showed moderate parenchymal alterations and the presence of a large number of round or irregularly oval microbodies (0.4-1 μ) delimited by unit membranes in the cytoplasm of the hepatocytes. These microbodies possessed a homogeneous matrix with a dense central crystalloid core and were remarkably similar to microbodies described in hepatocytes of rats and other species. Transverse section showed the dense crystalloid to be composed of regular arrays of 2 tubule-like structures. No explanation of a nucleoid structure in human liver microbodies can be given, nor can any correlation be made between the appearance of crystalloids in hepatic microbodies and remission of clinical symptoms.

- 8026 THE RELATIONSHIP BETWEEN MELENA AND HYPERBILIRUBINEMIA IN MATURE NEONATES (E.) Nelson, T. C. (U. Basel Child. Hosp., Switzerland). Biol. Neonat. 8(5-6):267-273, 1965.

Total serum bilirubin levels were determined (modified Jendrassik-Grof method) in 28 full-term newborns (wt. 2.5-4.16 kg) with clinical evidence of melena. A mean max. bilirubin level of 14.7 mg% was reached on day 6 of life. By comparison, max. levels of 5.8 mg% were reached on day 4 of life in healthy newborn controls. After 2 wk., the mean bilirubin conc. in infants with melena approached that of controls. It seems that the cause of hyperbilirubinemia in infants with melena is the absorption of bilirubin by the gastrointestinal tract following erythrocyte destruction.

- 8027 ASCENDING CHOLANGITIS. (E.) Furey, A. T. (St. Vincent's Hosp., New York, N. Y.). New York J. Med. 66(11):1299-1303, 1966.

The role of both obstruction and infection was studied in 51 patients (27 men and 24 women; av. age 63 yr. for males and 60 yr. for females) with ascending cholangitis observed from 1956-65. Of the 2 factors, obstruction seems to be the most important although most authors agree that both factors must be present to produce cholangitis. Four patients had been previously subjected to bypass surgery; 2 had choledochoduodenostomies and 2 had cholecystojejunostomies; subsequent surgery revealed stricture at the anastomosis site in 3 and autopsy revealed multiple liver abscesses in the fourth. Of the 51 patients, 9 nonoperative deaths occurred, 4 of which had had previous cholecystectomy; all showed multiple liver abscesses with associated common bile duct stones at autopsy. No operative deaths occurred, but 3 patients died postoperatively. In this series, 22 (43.1%) had had prior cholecystectomies; the period between first and second operations ranged from 5 mo. to 28 yr. (av. 6 yr.); 10 patients had common duct stones at subsequent common bile duct exploration; 2 other patients died without subsequent surgery and autopsy revealed common duct stones in association with multiple liver abscesses.

- 8028 PRECOCITY OF HEPATOCYTE DAMAGE AND REGENERATIVE HYPERPLASIA IN EXTRA-HEPATIC BILIARY OBSTRUCTION. EXPERIMENTAL AND CLINICAL STUDY. (Fr.) Stroun, J. (U. Geneva, Switzerland). Path. Microbiol. (Basel) 29(3):265-275, 1966.

LIVER AND BILIARY TRACT

Histological examination of liver tissue from 12 jaundiced patients (7 men and 5 women) with partial or complete extrahepatic biliary obstruction (1 of whom with agenesis of the gallbladder) and from rabbits subjected to ligation of the common bile duct showed similar hepatic damage. Early changes included edema and widening of the portal spaces, fibroblast proliferation, hyalinosis, and development of pseudo- and newly formed canaliculi. Parenchymal damage consisted of anisocytosis, anisokaryosis, cellular swelling and formation of clear spaces, well defined foci of hepatocyte necrobiosis, moderate steatosis, eosinophilic degeneration, pyknosis, and small foci of parenchymal regeneration. In rabbits, the extent of hepatic damage was greater and progression to cirrhosis and death occurred within 6 wk. The pathogenesis of hepatic damage is discussed, and differential diagnosis is made between the early forms of extrahepatic obstruction and toxic or viral hepatitis.

- 3029 CHRONIC IDIOPATHIC JAUNDICE (DUBIN-JOHNSON'S SYNDROME) IN THREE SISTERS. (E.) Blanck, C. (Karolinska Hosp., Stockholm, Sweden), S. Dahlgren, M. Gullmar-Willcocks and G. De Hevesy. *Acta Paediat. Scand.* 55(3):329-336, 1966.

Case histories are presented of 3 sisters (age 18, 16, and 11 yr.) with familial intermittent jaundice and elevated direct bilirubin. Two of them presented with slight, diffuse gastrointestinal symptoms and brown pigmentation of liver cells characteristic of the Dubin-Johnson syndrome. The third patient had a very mild form of jaundice and very little pigment in the liver cells. In this patient, diagnosis was not possible, being either a Dubin-Johnson syndrome, a Rotor syndrome, or an intermediate condition. Liver function tests were normal in all 3 patients. Histochemical analysis of the hepatic pigment seemed to indicate that it belongs to the lipofuscins.

- 3030 SURGICAL TREATMENT OF PORTAL HYPERTENSION IN INFANTS AND CHILDREN. (Fr.) Auvert, J. and C. Farge. *Gaz. Med. France* 73(11):2513-2526, 1966.
- Cirrhosis was observed in 30% of 162 infants and children observed over a 12-yr. period; etiology included congenital portal atresia in 54%, intrahepatic obstruction in 30%, and diffuse thrombophlebitis in 13%. Among 60 patients with portal malformation, results of surgery were as follows: good in 2 patients subjected to porta-caval shunt; 9 good, 2 failures, and 1 death of 12 cavomesenteric shunts; 3 good and 4 not evaluated of 7 cavo-ileo-mesenteric shunts; 3 late deaths, 7 failures, 24 good, and 7 not evaluated of 37 splenorenal shunts; good in 1 patient treated by mesentericocaval shunt; a patient treated by coronary-renal shunt was not evaluated. Among 27 patients with cirrhosis, results of surgery were as follows: 1 death, 1 good, and 3 not evaluated of 5 portacaval shunts; good in 1 patient treated by cavomesenteric shunt; 2 good and 2 not evaluated of 4 cavo-ileo-mesenteric shunts; 2 early and 3 postoperative deaths, 11 survivals for 3 yr. (3 died later), and 1 not evaluated of 17 splenorenal shunts. One patient with Budd-Chiari syndrome died as a result of cavomesenteric shunt. Among 5 patients treated by ligation of esophageal varices, 1 was lost to follow-up, 1 developed early recurrence of bleeding, 1 developed melena after 4 yr., and 2 showed no recurrence after 6 yr. In general, best results were observed following splenorenal (70% cures) and cavo-mesenteric shunt (85%).

- 3031 THE INFLUENCE OF STEROIDS ON SERUM BILIRUBIN, LEUCINE AMINOPEPTIDASE AND ALKALINE PHOSPHATASE IN EXTRAHEPATIC OBSTRUCTIVE JAUNDICE: THE POSSIBLE DIAGNOSTIC IMPORTANCE. (E.) Pruzanski, W. (Asaf Harofe Govt. Hosp., Zerifin, Israel). *Am. J. Med. Sci.* 251(6):685-689, 1966.
- In 10 patients with extrahepatic obstructive jaundice due to cancer of the pancreas, gallbladder, common bile duct, or ampulla of Vater (with or without liver metastases), treatment with prednisone (40 mg/day for 8 days) caused a significant increase (av. 50%) in serum leucine aminopeptidase levels in 7 patients, but had no significant effect on alkaline phosphatase except in 2 cases (decreases to 42% or 51% of the initial values). Serum bilirubin levels were variably affected; in 2 patients they fell by 43% and 57%, in 1 case they fell by 26%, in 2 cases they rose 14% and 30%, and in the other 5 they were between 94-109% of initial levels

LIVER AND BILIARY TRACT

at the end of treatment. In 9 patients with viral hepatitis of the obstructive type and in 5 patients with prolonged intrahepatic cholestatic jaundice of various origins, a significant decrease in bilirubin levels (to an av. of 39% and 50%, resp. of the initial values) was seen in all patients after 8 days of prednisone admin. Serum leucine aminopeptidase levels fell significantly in these patients (to an av. of 60% and 73% of control values, resp.), as did alkaline phosphatase levels (to an av. of 43% and 54% of control values, resp.). It is concluded that if 8 days of corticosteroid admin. leads to a decrease in serum bilirubin of less than 40%, with an increase in the already elevated serum leucine aminopeptidase levels, then extrahepatic obstruction of probable malignant origin may be suspected.

- 8032 RENAL EXCRETION OF DIPYRROLE SUBSTANCES IN MECHANICAL JAUNDICE. (Ger.) Netoušek, M. (City Hosp., Prague, Czech.), M. Moravec and O. Soušek. Blut 13(3):179-181, 1966.

In 50 men and women with obstructive jaundice of various origins (malignant or non-malignant), both fucsin and leukane were isolated from the urine in all cases. The total dipyrrole excretion ranged from 23-81 mg/24 hr. (av. 43.7 ± 15.2 mg/24 hr.). Total fucsin excretion was 16-66 mg/24 hr. (av. 34.4 mg/24 hr.); total leukane excretion was significantly smaller (4-27, av. 11 mg/24 hr.). The fucsin:leukane ratio ranged from 6:1 to 1:2. The highest values of total fucsin excretion were seen in patients with prolonged biliary tract obstruction and liver parenchymal damage, as well as those with jaundice originating in the liver parenchyma. The significance of the great variation in the fucsin:leukane ratio is unknown. A new quantitative assay method for urinary dipyrroles is described.

- 8033 SOME PROBLEMS OF THE PENICILLAMINE ACTION IN HEPATOLENTICULAR DEGENERATION. (E.) Chromy, K. (Postgrad. Inst. Med., Prague, Czech.) and A. Heyrovsky. Metabolism 15(6):529-536, 1966.

Treatment with D-penicillamine (900 mg/day; 2 courses; total 130 days) caused substantial clinical and neurological improvement after 150 days of treatment in a woman with Wilson's disease. Laboratory studies of serum and urinary copper excretion suggested that the decreasing cupriuretic effect of penicillamine (indirectly dependent on serum copper levels) and the decrease or normalization of basal copper excretion may not reflect a marked depletion of the very large copper stores in the body, but may rather be the direct result of a fall in the portion of filterable serum copper. Serum albumin and globulin levels were not affected, but a marked decrease of normal serum macroglobulin levels was noted.

- 8034 HEPATIC JAUNDICE IN CHRONIC CARDIAC INSUFFICIENCY. (Ger.) Nolte, D. (U. Kiel, Germany). Virchow. Arch. Path. Anat. 341(1):37-42, 1966.

Mild hepatogenic (parenchymatous) jaundice was demonstrable by histologic study of cryostat sections of unfixed liver in 22 of 47 autopsied adults in whom chronic vascular congestion of the liver was secondary to chronic cardiac insufficiency. There were no significant differences in terms of age or sex. The frequency of demonstrable incidence increased in direct proportion to the degree in which circulatory disturbances affected the liver tissues as such: e.g., such hepatogenic jaundice was demonstrable significantly more frequently among patients with a primary left cardiac disorder than among those with chronic cardiac insufficiency secondary to a pulmonary disorder; and significantly more frequently in the presence of hemorrhagic pulmonary infarct than in the presence of bronchial pneumonia. Cryostat sections permitted demonstration of the jaundice in 46.8% of the total group studied, while paraffin sections permitted it in only 12.8%.

- 8035 PRIMARY INTRACELLULAR CHOLESTASIS. AN ELECTRON MICROSCOPE STUDY INVOLVING TWO CASES OF DUBIN-JOHNSON SYNDROME AND ANICTERIC SUBJECTS TREATED WITH CHLORPROMAZINE. (It.) Barone, P. (U. Messina, Italy). Virchow. Arch. Path. Anat. 341(1):43-53, 1966.

In 2 brothers with Dubin-Johnson-Rotor syndrome and 8 schizophrenic subjects without jaundice, despite 1-3 yr. treatment with chlorpromazine, histologic and electron-microscopic studies of needle biopsies of the liver showed similar, characteristic

LIVER AND BILIARY TRACT

changes in the endoplasmic reticulum of the Golgi apparatus and in the pericanalicular zone. In addition to extensive intravacuolar storage of bile, these changes included areas of vacuolization, a significant diminution of the amount of archoplasm (with degenerative changes shown in the remainder), and a significant reduction of the number of mitochondria (accompanied by irregularities of form and, in some cases, by degenerative changes in the fibrillae). However, there was no evidence of obstructive or inflammatory processes in the bile ducts, nor of the presence of thrombi in the biliary capillaries. The author concludes that the intracellular cholestasis seen in both groups of patients was a primary disorder in its own right, resulting from a basic alteration of the cellular secretory mechanism which prevented excretion of bilirubin from the hepatic cells into the biliary capillaries.

- 036 HEPATIC BIOPSY SPECIMENS DERIVED NEAR THE SURFACE. COMPARATIVE STUDIES OF NEEDLE BIOPSY SPECIMENS AND SPECIMENS OF PARENCHYMA SURROUNDING THE BIOPSY SITE. (Ger.) Elster, K. (U. Erlangen-Nürnberg, Germany) and S. Hüttinger. Med. Welt (16):847-851, 1966.

The authors used autopsied subjects to make a series of comparative studies of Menghini-needle biopsy specimens derived at or near the hepatic periphery versus specimens of hepatic parenchyma surrounding the biopsy site to a distance of 2 cm on all sides and to a depth of 3-5 cm below the needle-biopsied area. Significantly different findings resulted sufficiently often to conclude that histologic diagnoses arrived at through needle biopsy of the peripheral areas of the liver are essentially unreliable. The serious discrepancies seen most frequently concerned the indicated extent and pathogenesis of fibrotic processes; the presence or absence, as well as the indicated extent of cirrhotic processes; and the presence or absence, as well as the indicated degree of passive hyperemia.

- 037 DIAGNOSTIC SIGNIFICANCE OF THE DE RITIS QUOTIENT. (Ger.) Kleine, F. D. (Acad. Med., Magdeburg, Germany). Deutsch. Zschr. Verdau. Stoffwechselkr. 25(6):355-362, 1966.

In acute hepatitis, the De Ritis quotient (the ratio of glutamic-oxalacetic to glutamic-pyruvic transaminase) ranged from 0.8-0.93 (median, 0.81), as compared to a range of 0.36-2.4 (median, 1.41) in obstructive jaundice, with the quotient in the latter disorder always more than 1.0, except during wk. 1 and 4 of illness. Statistically significant differences were found only during wk. 5 and 6, however, when the differences were considered most reliable in terms of differential diagnosis. Reliable differential diagnosis between other hepatic disorders required simultaneous consideration of absolute values for these 2 transaminase activities. During the first 4 wk. of illness, in the absence of significant differences in quotient, patients with hepatitis invariably showed higher levels of transaminase activity than did patients with obstructive jaundice (range for glutamic-oxalacetic transaminase: 81-122 and 27-60, resp.; range for glutamic-pyruvic transaminase: 11-161 and 18-84, resp.). During and after wk. 6 of illness, mean values for glutamic-oxalacetic transaminase activity in acute and chronic hepatitis were 33 and 2, resp., without significant differences in quotient or glutamic-pyruvic transaminase activity; those for posthepatic and cholangitic cirrhosis were 87 and 50, resp., without significant differences in quotient or glutamic-pyruvic transaminase activity; while the mean value for glutamic-oxalacetic transaminase in hepatic dystrophy was 124 (against a mean value of 123 for glutamic-pyruvic transaminase). At this time, the mean quotients for acute and chronic hepatitis were 0.73 and 0.98, resp., while those for the cirrhoses and hepatic dystrophy ranged from 2.6-3.8. It is concluded that simultaneous determinations of the De Ritis quotient and the absolute values for these 2 types of transaminase activity are a valuable adjunct to differential diagnosis of hepatic disorders.

- 038 INDICATIONS AND OPERATIVE RISK IN PORTACAVAL ANASTOMOSIS. (Ger.) Hamelmann, H. (U. Munich, Germany) and J. Nitschke. München. Med. Wschr. 108(14):747-751, 1966.

Based on studies of 76 patients undergoing portacaval anastomosis for portal hypertension, the authors have constructed a weighted index of criteria for determining

LIVER AND BILIARY TRACT

the degree of operational risk to be anticipated. Specific criteria (with their "point values") are as follows: previous coma or state approaching coma (6), aged 60 or over (4), more than 1 recurrence of bleeding (4), treatment-resistant ascites (6), transient ascites (3), total serum bilirubin >2 mg% (5), total serum bilirubin 1.2-2.0 mg% (3), serum albumin 3.0 g% or less (4), prothrombin index 50% or less (4), Takata Test 50 mg% or less (4), platelet count 10^5 or less (2), edema of the extremities (2). A total point count of 12-17 indicates that the risk and the chances of success are approx. equal. When the index was used to select 19 cirrhotic patients with portal hypertension for surgery, there was only 1 mortality and that was in the postoperative stage. Among 57 patients operated previously (50 portacaval and 7 splenorenal anastomotic shunts) and selected by conventional criteria, operational mortality had been 30%.

- 8039 PORTAL VENOGRAPHY BY SELECTIVE ARTERIAL CATHETERIZATION. (E.) Nebesar, R. A. (Harvard Med. Sch., Boston, Mass.) and J. J. Pollard. Am. J. Roentgen. 97(2):477-487, 1966.

Adequate visualization of the portal system was obtained in 39 of 46 patients by instillation of relatively large doses of contrast agent into the splenic, celiac or superior mesenteric artery by means of a catheter, usually via the femoral artery but occasionally via the left brachial or axillary route. Indications included suspected portal hypertension, suspected thrombosis of the portal vein, need for confirmation of the patency of a previous shunt or need for confirmation of the patency of the portal vein prior to constructing a portacaval or splenorenal shunt. The technic is particularly recommended for cases in which splenic pulp puncture is contraindicated: e.g., patients with low prothrombin time or low platelet count with ascites, or with splenomegaly secondary to an infection. Contraindications include severe, but not mild, bleeding states. Catheterization of the superior mesenteric artery is said to be the safest, most reliable and easiest method of producing diagnostic splenoportograms in splenectomized patients. Placing the tip of the catheter into the hepatic or celiac artery permitted the making of a hepatic angiogram. In general, selective catheterization with inj. of the splenic artery was considered preferable, but when this was unsuccessful, selective superior mesenteric arterial inj. usually produced comparable results.

- 8040 LOW MOLECULAR WEIGHT DEXTRAN AND HIGH PRESSURE OXYGEN IN THE TREATMENT OF LIGATION OF THE HEPATIC ARTERY IN DOGS. (E.) Hogan, J. P. (Marquette U. Sch. Med., Milwaukee, Wis.) and E. H. Ellison. Am. J. Surg. 111(6):873-876, 1966.

In adult mongrel dogs, following a cholecystectomy and hepatic arterial ligation, the treatment of choice (100% survival) consisted of procaine penicillin and streptomycin. Postoperative treatment with hyperbaric oxygen or low molecular wt. dextran gave a survival rate of 12% and 38%, resp. However, when 100% oxygen was admin. simultaneously with low molecular wt. dextran, the survival rate rose to 50%. Only 19% of untreated control dogs survived. Measurement of the oxygen pressure in the portal vein and femoral artery showed high oxygen tensions were achieved during the hyperbaric oxygen treatment. Postmortem cultures demonstrated clostridia of an undetermined species in the liver and peritoneal fluid.

Hepatic Injury

- 133 EXPERIMENTAL PORPHYRIA INDUCED IN WHITE RATS BY THE ADMINISTRATION OF ETHIONINE. (Fr.) Palma Carlos, A. (Charity Hosp., Paris), M. L. Palma Carlos, M. Gajdos-Török and A. Gajdos. Rev. Franc. Etud. Clin. Biol. 11(3):284-290, 1966.
- Porphyrin metabolism was studied in female white rats (wt. 200 g) fed a low-protein diet (8% casein) containing 0.5% ethionine for 3 wk. (Group 1); a low-protein diet (12% casein) and 50 mg/day of ethionine by stomach tube for 1 wk. (Group 2); a balanced diet (18% casein) and 100 mg/day of ethionine by stomach tube for 2 consecutive days (Group 3). A 40-50% decrease in the hepatic conc. of ATP was observed in each of the treated groups. In treated animals, urinary excretion of δ -aminolevulinic acid, uroporphobilinogen, and coproporphyrin was increased, without the appearance of detectable quantities of uroporphyrin in the urine. Fecal copro- and protoporphyrin levels were markedly increased. At the end of treatment, increased levels of hepatic and RBC proto- and coproporphyrin were observed. Av. hepatic total lipid content increased to 6.8 g/100 g of fresh tissue in animals of Group 3 as compared to 3.8 in controls. Ethionine-induced porphyria was found to differ from porphyria induced by other substances (allylisopropylacetylcarbamide, hexachlorobenzene, diethyl-1,4-dihydro-3,5-dicarboxypyridine, griseofulvin, 6-mercaptopurine, and orotic acid) in the following ways: (1) δ -aminolevulinic acid-synthetase activity in liver mitochondria remained normal and (2) the admin. of adenosine-5'-monophosphoric acid, inosine, or ATP failed to influence the disturbances in porphyrin metabolism. The production of experimental porphyria following the decrease in hepatic levels of ATP caused by ethionine provides further evidence in favor of the regulatory role which this nucleotide plays in the biosynthesis of porphyrins.
- 134 EFFECT OF VARIOUS CATIONS ON THE IN VITRO INACTIVATION OF MICROSOMAL GLUCOSE-6-PHOSPHATASE BY CCl_4 . (It.) Comporti, M. (U. Siena, Italy) and G. A. Rita. Boll. Soc. Ital. Biol. Sper. 42(5):228-231, 1966.
- The protective effect of various cations on the in vitro activation of microsomal glucose-6-phosphate by CCl_4 was studied in saccharose suspensions of microsomal sediment containing soln. of $\text{CoCl}_4 \cdot 6\text{H}_2\text{O}$, anhydrous CaCl_2 , $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$, and $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ reincubated in Warburg flasks for 20 min. at 37°C . CCl_4 was added to the incubation mixture through the lateral arm of the flask in quantities of 135 or 330 $\mu\text{g}/\text{ml}$ during the preincubation period. The cations Ca^{++} , Mg^{++} , and Mn^{++} showed a marked protective effect against enzyme inactivation especially at the higher conc. of CCl_4 , while Co^{++} had no effect. No significant variations were observed in the amount of CCl_4 dissolved in the microsomal suspension upon addition of the various cations during preincubation, except for Ca^{++} at a conc. of 10^{-3} M, which caused a decrease in the solubilization of CCl_4 of 18% and 4% at doses of 135 and 330 $\mu\text{g}/\text{ml}$, resp. However, it is improbable that this slight decrease in solubilization is by itself responsible for the decreased inactivation of the microsomal enzyme. In fact, at a conc. of 10^{-4} M, Ca^{++} shows marked protection against enzyme inactivation without affecting CCl_4 solubilization. Among the possible explanations of the effect of these cations is protection of active -SH groups of glucose-6-phosphate against the effects of CCl_4 .
- 135 EFFECTS OF THE TIME INTERVAL ON THE WAYS IN WHICH THE LIVER REACTS TO REPEATED ADMINISTRATIONS OF CARBON TETRACHLORIDE IN ANIMAL EXPERIMENTS. (Ger.) Vido, I. (Charles U., Bratislava, Czech.) and J. Vido. Med. Pharmacol. Exp. (Basel) 14(4):395-400, 1966.
- In mongrel dogs, two inj. of carbon tetrachloride (0.5 ml/kg/dose of a 1:4 olive oil suspension) at an 11-day interval induced prolonged, very marked increase of serum alkaline phosphatase, glutamic-pyruvic transaminase and glutamic-oxalacetic transaminase activity, the first 2 maintaining abnormal levels throughout a 40-day observation period and the last maintaining abnormal levels throughout half the period. (A transient, but abnormal, rise of serum bilirubin was also observed between day 13-16.) These effects lasted several times as long as those induced by single admin. However, repeated, intermittent admin. over a long period of time resulted in a gradual normalization of serum levels of all 3 enzymes, which was followed occasionally by a further decrease to below-normal levels.

LIVER AND BILIARY TRACT

Hepatic Injury

- 8136 LIVER DAMAGE FROM ORAL CONTRACEPTIVES. (E.) Stoll, B. A. (Peter MacCallum Clin., Melbourne, Australia), J. T. Andrews and R. Motteram. Brit. Med. J. 1(5493):960-961, 1966.

Four postmenopausal females were given 6 tablets/day of Lyndiol (5 mg lynoestrenol plus 0.15 mg mestranol) as therapy for advanced breast cancer and liver function was studied at 2-wk. intervals for 56 days. At 14 days and continuing over the test period there were abnormally high serum glutamic oxalacetic transaminase (I) and serum isocitric dehydrogenase levels in all 4 patients. Clinical jaundice and a high bilirubin level were found in 2 cases while alkaline phosphatase and serum protein levels were normal. Liver biopsies in all 4 cases indicated parenchymal cell necrosis. The abnormal values fell to normal within 8 wk. in 2 patients taken off therapy and in the 2 continued on the drug, the values decreased but did not return to normal. Lynoestrenol, the progestogen component, was given alone to 7 patients, 30 mg/day, and during the 56-day test period, 3 had moderately elevated I but no increase in serum bilirubin. Liver biopsy in 2 cases demonstrated the presence of parenchymal cell necrosis to a lesser extent than was seen in the Lyndiol-treated cases. None of 4 patients given Mestranol, 0.9 mg, had a rise in I or serum bilirubin.

- 8137 JAUNDICE AFTER MEDICATION WITH BIRTH CONTROL TABLETS. (Sw.) Lundbergh, P. (Epidem. Hosp., Stockholm, Sweden). Laekartidningen 63(8):711-715, 1966.

Eighteen women developed jaundice after receiving peroral contraceptives over periods of less than 1-15 mo. One medication contained only progestogens; the others contained combinations of substances resulting in both estrogenic and progestational activity. A significant degree of biliary stasis was shown by all who underwent hepatic biopsy, while almost all of the patients showed significant increases of serum bilirubin, transaminase, cholesterol and beta-globulins. Less frequently seen were increased levels of thymol, zinc sulfate and alkaline phosphatase. In all but 2 of the patient group, all values were normalized within 1 mo. after medication was terminated. Four of 5 who renewed the medication at a later date developed an almost immediate, progressive increase of serum transaminase levels, which reversed spontaneously following withdrawal.

- 8138 LIVER FINDINGS IN ACUTE PHOSPHORUS POISONING IN MAN. (Ger.) Salfelder, K. (U. Los Andes, Merida, Venezuela), C. Seelkopf and G. V. Inglessis. Zbl. Allg. Path. 108(5):524-529, 1966.

Autopsy findings in 14 cases of fatal phosphorus poisoning included typical, diffuse multiple areas of generalized necrosis throughout the hepatic lobes. These were accompanied by numerous, newly-formed biliary canaliculi in the periportal fields; which, in turn, were grossly extended to surround the lobes as they do in the livers of swine. There were numerous biliary thrombi in the intralobular bile ducts and canaliculi. In several cases, fairly extensive, yellow areas were observed in the liver tissue, usually accompanied by fatty degeneration, necrosis in the central area and numerous biliary thrombi. However, in a 14-year-old girl who had been receiving a rauwolfia preparation prior to her suicide attempt, the tissue within these yellow areas was virtually intact, although innumerable biliary thrombi were in evidence. The authors suggest that this may indicate that the poison does not necessarily attack the liver cells directly, but induces preliminary (or concurrent) regional, circulatory disturbances which are then followed by hypoxia but which, meanwhile, result in varying concentrations or amounts of active toxin. The possibility that the rauwolfia preparation may have reduced the catecholamine level (by blocking the postganglionic sympathetic nerve fibers in the region of their neuromuscular terminals) and thus maintained more or less normal circulation in the areas in question could not be excluded.

- 8139 INFLUENCE OF LIVER FUNCTION STATUS ON THE CONJUGATION OF SULFOBROMOPHTHALEIN. (Ger.) Grisk, A. (U. Greifswald, Germany) and U. Behrend. Acta Biol. Med. German. 16(1):31-42, 1966.

Following a 2-hr., continuous infusion of sulfobromophthalein sodium, (I) in vivo,

LIVER AND BILIARY TRACT

Hepatic Injury

glutathione (II) content was reduced significantly in rat liver, but not in the blood. A similar, but less marked reaction followed perfusion with I-monothio-glycerine. Reduction of hepatic II was paralleled by increase of I conjugates in the bile, including I-II, I-(II)₂ and conjugates formed with cysteine, alanine, glycine and the glutamic acids. I-cysteinyl-glycine and unconjugated I were also found. In the winter months, the rate of conjugation was considerably lower than that seen in the summer. The total quantity of I conjugates found in the bile was not affected by hexobarbital, ether or urethan narcosis, although it was decreased significantly under chloroform. Under hexobarbital or ether, the rate of I-elimination into the bile was accelerated, as compared to elimination under urethan or particularly) chloroform. When I-II, I-cysteine or I-monothioglycerine were inj. instead of free I, the elimination rate into the bile was also decreased. Pre-treatment with phenobarbital or phenobarbital + SKF 525-A (diethylaminoethyl-di-phenylpropyl acetate) accelerated elimination and improved the I-balance simultaneously, without affecting either the quantity or the quality of I conjugates. A significant effect was exerted by SKF 525-A, alone, or by dehydrocholic acid, alpha-monosuccinic acid or l-phenyl-propanol.

- 140 HEPATIC SINUSOIDS IN CARBON TETRACHLORIDE-INDUCED CIRRHOSIS. AN ELECTRON MICROSCOPIC STUDY. (E.) Stenger, R. J. (Cleveland Metrop. Gen. Hosp., Ohio). Arch. Path. (Chicago) 81(5):439-447, 1966.

vascular alterations along the hepatic sinusoids were studied by electron microscopy in female Holtzman rats after treatment for 5-35 wk. with CCl₄ (0.4 ml of a 50% soln. in olive oil s.c. twice a wk.). While many of the hepatic sinusoids remained structurally unaltered, observed changes included the formation of prominent Kupffer cells, the development of capillarized sinusoids, and the appearance of new vascular channels in fibrotic bands between parenchymal cell cords. The hypertrophied Kupffer cells, whose most prominent feature was a large number of polymorphic phagosomes, are considered to result from the tissue injury and cellular necrosis induced by repeated admin. of CCl₄. The capillarized sinusoids and the new vessels in the fibrotic bands appeared as closed circulatory pathways encompassed by basement membrane-like structures, as opposed to the open circular paths seen in normal rat hepatic sinusoids. Changes are presumed to represent circulatory disadvantages to the hepatic parenchyma.

- 141 CHANGES IN RAT LIVER CELLS INDUCED BY OROTIC ACID FEEDING. (E.) Novikoff, A. B. (Albert Einstein Coll. Med., New York, N. Y.), P. S. Roheim and N. Quintana. Lab. Invest. 15(1)(Pt. 1):27-49, 1966.

In rats fed orotic acid for 7 days, there was no decrease in the incorporation of ¹⁴C-amino acids into liver proteins; total plasma proteins and plasma high-density lipoproteins were unchanged, but the low-density lipoproteins fell markedly and the very low-density lipoproteins almost disappeared. Electron microscope studies showed extensive breakdown of the endoplasmic reticulum of the liver cells after 7 days of orotic acid feeding. Lipid droplets appeared near the endoplasmic reticulum and later became widespread. After addition of adenine to the orotic acid, these lipid droplets regressed; during this time, the Golgi apparatus became very active. Liver cells of rats admin. orotic acid alone or with adenine also showed a system of smooth membranes resembling the lysosome-Golgi apparatus-endoplasmic reticulum complex also noted in neurons and other cell types. Dilated regions of the endoplasmic reticulum containing electron-opaque material were seen in this region.

- 142 BIOCHEMICAL STUDIES ON FATTY LIVER. III. CHANGES OF THE ENZYME ACTIVITIES IN FATTY LIVERS INDUCED BY AN AMINO ACID IMBALANCE. (E.) Ogura, M. (Utsunomiya U. Sch. Agr., Japan). Agr. Biol. Chem. 30(3):226-231, 1966.

In rats fed a high-calorie, low-protein (8%) casein diet, liver serine dehydrase activity decreased to less than 5% of control levels; there was no significant difference in this respect between control rats and animals fed the experimental diets. In rats with fatty liver induced by feeding 0.3% DL-methionine (threonine deficiency) and in animals fed DL-methionine supplemented with 0.38% L-threonine, homoserine

LIVER AND BILIARY TRACT

Hepatic Injury

dehydrase activity was significantly decreased as compared to controls. There was no significant difference between the 2 experimental groups in this respect, although the liver fat content was significantly lower in animals fed the threonine-supplemented diet than in the methionine-treated animals (av. 17.42% and 24.39%, resp., after 3 wk.). There was no significant change in threonine aldolase activity in any of these groups. Since the enzyme levels were apparently unrelated to the development of fatty liver, it is suggested that the calorie content or the protein level of the diet was responsible for the changes observed.

- 8143 CASE HISTORY OF SEVERE CARBON TETRACHLORIDE POISONING. (Ger.) Laubinger G. (St. Georg Gen. Hosp., Hamburg, Germany). *Med. Klin.* 61(19):753-756, 1966.

The initial symptom of CCl_4 poisoning (in a woman who took about 200 ml in a suicide attempt) was transient narcosis, followed by severe gastrointestinal toxic reaction (reaching a max. after 2 days, with recovery after 2 wk.). Severe kidney damage appeared on day 2, with gradual recovery over the next few days. Severe liver damage appeared simultaneously; the serum transaminases were normalized after about 3 wk., but histological damage was still apparent after 5 wk. The patient also developed a normo- to slightly hypochromic anemia after 17 days, which subsided without specific therapy after 4 mo. Treatment consisted of liver substitutive therapy, vitamins, fluid and electrolyte replacement, and antibiotics. The patient was clinically well after 2 wk.

- 8144 CHANGES IN RNA IN THE RAT LIVER DURING THIOACETAMIDE APPLICATION. (Ger.) Meyer, J. G. (U. Wurzburg, Germany). *Zschr. Naturforsch.* 21b(4):342-351, 1966.

After treatment with thioacetamide, the nucleolar RNA of rat liver was altered to the ribosomal type, as shown by density gradient centrifugation. Cytoplasmic RNA was preponderantly of the 28S type. The 65° fraction of normal nuclei (corresponding to messenger RNA) was labeled with C^{14} -orotic acid to the greatest extent in the 8S region; after thioacetamide treatment most of the label was found in the 18S region. The 50° fraction of thioacetamide-poisoned cells showed a higher specific activity in the 12S fraction than did the corresponding fraction from normal cells. The uptake of C^{14} -orotic acid into the extractable cytoplasmic (ribosomal) RNA was delayed after thioacetamide treatment. The proposed mechanism of these changes, an inhibition of the polysome-forming mechanism, is discussed.

- 8145 CHANGES IN NUCLEAR NUCLEIC ACIDS IN RAT LIVER AFTER CARBON TETRACHLORIDE POISONING. (Ger.) Richter, G. (U. Jena, Germany), D. Katenkamp, B. Oettinger and S. Michel. *Acta Biol. Med. German.* 16(3):319-322, 1966.

At 18 hr. after CCl_4 poisoning, P^{32} incorporation into RNA decreased in proportion to the increase in DNA in rat liver nuclei. These changes were much smaller in Fraction I than in Fraction II (an increase of 2- and almost 5-fold, resp.). The relative specific activity of messenger RNA was only slightly increased; that of ribosomal RNA was increased to a much greater extent. Early in the study, about 30% of all ribosomes attached to the ergastoplasmic membrane disappeared; the protein synthetic capacity of the remaining membrane system was also reduced. After 24 hr., when *de novo* DNA synthesis began, the relative specific activity of RNA II was high (increased almost 3-fold); inhibition of ribosomal and stimulation of messenger RNA was apparent.

- 8146 LIVER NECROSIS FROM PARACETAMOL. (E.) Boyd, E. M. (Queen's U., Kingston, Ontario, Canada) and G. M. Bereczky. *Brit. J. Pharmacol.* 26(3):606-614, 1966.

The p.o. acute LD₅₀ of the phenacetin metabolite, paracetamol, in rats was 3.71 ± 0.83 g/kg (compared to 1.65 ± 0.35 g/kg reported for phenacetin); the minimum LD₁₀₀ was 6.5 ± 0.8 g/kg, and the max. nonlethal dose was 0.9 ± 0.8 g/kg. The survival time at high doses varied inversely with dosage, but the range of times was wide. The median survival time at the LD₅₀ was 21 hr. Immediate toxic symptoms were listlessness, decreased response to stimuli, tail extension, tremor, and pallor;

LIVER AND BILIARY TRACT

Hepatic Injury

During the first 24 hr., the symptoms resembled the toxic reactions to phenacetin. The animals died of respiratory failure, with deep hypothermic stupor, extensive capillary-venous congestion, centrilobular hepatitis and tubular nephritis. In animals that died after 1-7 days, the liver lesions progressed to hepatic necrosis and were associated with degenerative changes in the brain, kidneys, and arterioles. Surviving rats demonstrated signs of recovery after 2 or 3 days.

- 147 CORTISONE-INDUCED LIPAEEMIA AND HEPATIC STEATOSIS IN THE MALE RAT. (E.) Hill, R. B., Jr. (U. Colorado Sch. Med., Denver) and F. P. Rudé. Nature (London) 210(5037):733, 1966.

In male albino rats fed a standard liquid diet, treatment with cortisone (6.25 mg/day i.p.) resulted in a marked wt. loss (pair-fed control animals gained wt.). After 2 wk. of treatment, av. serum glycerides in treated and control rats were 3.42 and 1.42 mmol/1000 ml serum, resp., and av. liver glycerides were 0.850 and 0.208 mmol/g liver protein, resp. The increase in serum and liver glycerides was of the same order of magnitude as that seen in similarly treated female rats, showing that there is no sex difference in the fatty acid-mobilizing properties of cortisone in rats.

- 148 EFFECTS OF SLOW AND RAPID THAWING ON NUCLEAR STRUCTURE OF RAPIDLY FROZEN MOUSE HEPATIC PARENCHYMAL CELLS. (E.) Young, D. E. (Armed Forces Inst. Path., Washington, D. C.), E. A. Arnold and R. E. Stowell. Lab. Invest. 15(2):381-402, 1966.

AF₁ mouse liver frozen rapidly at -155°C was thawed at 2°, 24°, and 37°C, and the tissues were compared to unfrozen controls by light and electron microscopy. In general, no differences were noted in the degree of cellular swelling or narrowing of vascular space in any of the 3 thawing conditions; hemolysis was increased at lower thawing rates. Changes at 24°C resembled those at 37°C but tended to be slightly more pronounced. Changes in parenchymal cell nuclei after thawing at 24° or 37°C were similar and varied from no observable change to rather marked changes in size, shape, and staining characteristic. As compared with more rapidly thawed nuclei, at 2°C distortion of nuclear profiles and focal separation of nuclear membranes were more pronounced. The perinuclear halo, however, was less prominent. Aggregation of chromatin along the nuclear membrane, condensation of chromatin and of interchromatin and perichromatin granules in the peripheral nucleoplasm, and the obliteration of nucleolar structure were all more advanced. Breaks in the nuclear envelope were rarely seen. The most distinctive feature of slowly thawed nuclei was the occurrence of intranuclear spaces showing different geometric shapes. The mechanism of damage to cells from freezing and thawing is discussed without further clarification of the relative role of mechanical ice crystal effects versus altered ionic concentration or pH.

- 149 FORMATION OF BILIRUBIN IN NORMAL, DAMAGED, AND GUNN RAT LIVERS. (E.) Rodríguez Garay, E. A. (Mayo Clin., Rochester, Minn.), C. A. Owen, Jr. and E. V. Flock. J. Lab. Clin. Med. 67(5):817-829, 1966.

Bilirubin formation was studied in isolated perfused livers from normal and Gunn rats, in acutely damaged livers from rats receiving i.p. inj. of a single dose (0.06 ml/100 g body wt.) of CCl₄, and in regenerating livers from rats subjected to 70% hepatectomy at various times previously. Significantly larger amounts of biliary bilirubin were excreted by CCl₄-intoxicated rats and their livers than in controls. C¹⁴-δ-aminolevulinic acid incorporation into the biliary bilirubin excreted by normal, CCl₄-treated, and regenerating livers ranged from 12-14%, 13-16%, and 9-15%, resp., during 5-hr. perfusions. Isolated perfused livers from Gunn rats incorporated approx. 5% of the labeled acid into plasma bilirubin. The specific activity of biliary bilirubin excreted by normal livers showed a peak at 5 hr. with perhaps a secondary increase at 15 hr.; CCl₄-treated livers showed only the first peak. In CCl₄-treated livers, Fe⁵⁹-labeled hemoglobin was sequestered at a higher than normal rate, while the rate of hemolysis was the same as that of normal livers. The incorporation of C¹⁴-δ-aminolevulinic acid into partially purified, hepatic, nonhemoglobin hemes suggest that these represent intermediates

LIVER AND BILIARY TRACT

Hepatic Injury

in the formation of bilirubin in the liver. With CCl_4 -treated livers, there was a diminished incorporation of C^{14} into hepatic heme compounds.

8150 EXPERIMENTAL COPPER POISONING AND WILSON'S DISEASE. (E.) Williams, A. O. (Queen's U., Belfast, Ireland). *Irish J. Med. Sci.* 6(484):133-140, 1966. Admin. of copper acetate (0.2% soln. as drinking water) for 320 days resulted in no significant increase in serum ceruloplasmin (copper oxidase) levels in rats, but caused a significant increase (by an av. of 15.97, 13.9 and 28.13 $\mu\text{g/g}$ wet wt., resp.) in the liver, kidney and brain. Amino acid excretion patterns after 100 or 300 days of chronic copper poisoning showed a pattern similar to that noted in live damage; the increase in amino acid excretion was particularly marked in the case of glutamic acid and methionine. No copper was demonstrable histochemically in the liver, kidney or brain tissues of untreated rats, or in the brains of chronically poisoned animals; 7 of the 12 test animals demonstrated small conc. of copper in the proximal tubules of the kidney. The distribution of copper in the liver tissue was variable. The lobular architecture of the liver was preserved. Some areas of focal hepatic necrosis were noted, but there was no diffuse fibrosis, cirrhosis, or regeneration, the essential reticulin framework was intact, and no lesions were noted in the portal tracts. The spleen showed moderate amounts of pigment (hemosiderin) in the periphery of the Malpighian body. Slight histological changes were noted in the kidney; no lesions were noted in the intestine or brain. Serum protein changes resembled those seen in moderate liver damage, possibly because a few areas of focal hepatic necrosis were present.

8151 NH_3 METABOLISM AND BACTERIAL COUNT IN THE INTESTINAL CANAL OF RABBITS EXPERIMENTALLY INDUCED LIVER DAMAGE. (Jap.) Imaizumi, T. (Nagoya U. Sch. Med., Japan). *Nagoya Igaku (J. Nagoya Med. Assn.)* 88(1):64-85, 1965.

The effect of CCl_4 -induced acute and chronic liver damage or chemotherapeutic agent (achromycin, streptomycin, ergothioneine) on ammonia metabolism and bacterial count was studied in rabbit intestine. No significant change in bacterial count was seen in animals with acute liver damage, while marked increases in the number of *Escherichia coli* and *Enterococcus* were observed in animals with chronic liver damage; bacterial count decreased after admin. of chemotherapeutic agents. Largest amounts of ammonia were found in the large intestine, cecum, ileum, and jejunum (in decreasing order); ammonia levels were markedly increased in chronic liver damage and decreased by admin. of chemotherapeutic agents at all intestinal sites. Blood ammonia showed no increase in acute liver damage; both portal and peripheral blood levels were increased in chronic liver damage; the admin. of chemotherapeutic agents decreased ammonia levels markedly in portal blood but not in peripheral blood. In chronic liver damage, urea nitrogen levels were decreased in the urine but unchanged in the blood; in acute liver damage, both urinary as well as blood levels of urea nitrogen were the same. Liver arginase activity was markedly decreased in both types of liver damage but not affected by chemotherapy. Neither liver damage nor chemotherapeutic agents influenced intestinal pH.

8152 EFFECT OF EXTRACT PREPARED FROM REGENERATING LIVER ON LIVER REGENERATION IN RATS POISONED WITH CARBON TETRACHLORIDE. (E.) Balázs, M. (U. Budapest, Hungary), I. Magyar, R. Richter and J. Valu. *Gastroenterologia (Basel)* 105(4):214-224, 1966.

Rats were treated with CCl_4 for 7 mo., followed by 3 mo. of treatment with CCl_4 and various rat liver extracts. An extract of normal tissue prepared by autolysis with CCl_4 gave the least protective effect; 6 of the 20 animals died during treatment. The extent of regeneration was described at Stage I (100%) in 4 rats, Stage II (about 75% of cells) in 3, Stage III (about 50% of cells) in 2, and Stage IV (no regeneration, with marked hydropic degeneration) in 5 animals; the lack of healing may explain the low incidence of fibrosis and cirrhosis in this group (2 and 1, resp.). After admin. of an extract of normal liver tissue, the extent of regeneration was described as Stage I, II, III, and IV in 8, 5, 0, and 3 rats, resp.; 4 animals died. Cirrhosis was present in 4 animals showing Stage I

LIVER AND BILIARY TRACT

regeneration; moderate to marked fibrosis was seen in 8 rats. The best protection was afforded by an extract from the livers of CCl_4 -poisoned rats. In this group, 3 rats died; liver regeneration was described as Stage I, II, and III in 4, 12, and 12 rats, resp. Cirrhosis was present in 5 animals, and marked to moderate fibrosis in 12 rats. A regenerative humoral factor is postulated to account for these results.

- 53 MODE OF PROLIFERATION IN CIRRHOTIC RAT LIVER AFTER PARTIAL HEPATECTOMY. AUTORADIOGRAPHIC STUDIES WITH H^3 -THYMIDINE. (Ger.) Stöcker, E. (U. Wurzburg, Germany), V. Höper, S. Plato and W. D. Heine. Klin. Wschr. 44(11): 657-658, 1966.

Rats were treated for 436 days with thioacetamide (30 mg% in drinking water); 18 days after the end of treatment, partial hepatectomy was performed, followed by admin. of H^3 -thymidine; the animals were sacrificed after 24 hr. Three types of pseudoacini and regenerating nodules were seen in the cirrhotic livers: areas of nodules with markedly basophilic cytoplasm and little DNA synthesis (av. mitotic index and H^3 incorporation index 0.043% and 2.66%, resp.); acini with many weakly basophilic nuclei, RNA-poor cytoplasm, and Kupffer cells (mitotic index and H^3 -incorporation significantly higher than in the first type of cells: 0.53% and 7.39%, resp.); and areas of an intermediate degree of regeneration. The H^3 -incorporation index and the rate of DNA synthesis were both much higher in regenerating liver from untreated rats than in liver from rats with thioacetamide-induced cirrhosis. There was no evidence for an increase in the rate of DNA synthesis or shortening of the S phase in regenerating cirrhotic liver.

- 54 STUDIES IN EXPERIMENTAL ANIMALS ON THE PATHOGENESIS OF FATTY LIVER AFTER CHRONIC ALCOHOL ADMINISTRATION. (Ger.) Ammon, H. P. T. (U. Erlangen-Nürnberg, Germany) and C. J. Estler. Klin. Wschr. 44(11):651-652, 1966.

In mice treated with a 15% (wt./vol.) alcohol soln. (as drinking water) for 6 mo., the serum levels of free and esterified fatty acids increased by approx. 50% and 70%, resp., while the hepatic fat content rose about 30%. Treatment with alcohol, followed by the β -adrenolytic agent 1-(isopropylamino)-3-(m-tolyloxy)-2-propanol (50 mg/kg s.c., 24 hr. before sacrifice), caused a marked decrease in liver fat (to about 40% of control levels) and a slight decrease in the elevated serum free fatty acids (to about 140% of control levels), but the serum esterified fatty acids remained substantially unchanged. It is concluded that activation of adipose tissue lipase by chronic alcohol admin. (which causes an increase in catecholamine liberation) is implicated in the pathogenesis of fatty liver due to prolonged alcohol consumption.

- 55 SIGNIFICANCE OF NUTRITIONAL STATUS FOR THE DEVELOPMENT OF DIETHYLNITROSAMINE-INDUCED HEPATOMAS IN RATS. (Ger.) Osswald, H. (German Cancer Ctr., Heidelberg) and D. Schmähl. Naturwissenschaften 53(10):255-256, 1966.

In BR 46 albino rats treated with diethylnitrosamine (3 mg/kg/day in drinking water), and fed either a normal commercial diet or a diet of the same composition but reduced in quantity (to about 25% of normal), there was no significant difference in the av. total tumor-inducing dose of the carcinogen (600 ± 100 and 650 ± 80 mg/kg, resp.) or the av. time required to induce hepatomas (200 ± 33 and 217 ± 27 days, resp.). The incidence of hepatomas in both groups was also the same (96% and 94%, resp.); 5 animals in the former group also developed squamous cell carcinomas of the ear, and 4 rats in the latter group also developed esophageal tumors. The liver tumors in both groups were histologically the same, ranging from hepatocellular carcinomas to highly differentiated hepatomas. The mortality rate before the development of palpable tumors was higher in the deficient-diet group; most of these animals died of cachexia.

- 56 CYTOLOGICAL CHANGES IN RAT LIVER IN EARLY STAGES OF ACUTE CARBON TETRACHLORIDE HEPATOPATHY. (E.) Sachdev, K. N. (S. M. S. Coll. Med., Jaipur, India). Indian J. Path. Bact. 9(2):188-197, 1966.

In rats treated with CCl_4 (1.8 ml/kg s.c.), the liver architecture was preserved throughout the 18-hr. study. The ribonucleoproteins were altered as early as 1 hr.

after treatment (especially the diffuse cytoplasmic ribonucleoproteins), whereas the nuclei were not affected at this time and the mitochondria showed no change until 6 hr. after treatment. Development of "balloon cells" in the initial stages was noted as early as 6 hr. after treatment; these cells were distributed in all parts of the lobule, even periportally, in contrast to the classical midzonal location. The mitochondria of affected cells were reduced in number, swollen, and rounded after 12 hr. Well-developed balloon cells were present at 18 hr.

- 8157 AGE AS A MODIFYING FACTOR OF ACUTE HEPATIC INJURY IN ALBINO RATS. (E.) Mehrotra, R. M. L. (K. G. Med. Coll., Lucknow, India) and U. C. Chaturvedi. Indian J. Path. Bact. 9(2):182-187, 1966.

Acute liver injury was produced by CCl_4 (0.15 ml/100 g, single s.c. inj.). No cytological injuries to liver cells were seen in rat fetuses (treated by admin. of the poison to the mother) and only minimal cellular injury was seen in rats treated 1, 3, or 7 days after birth. Cellular damage of increasing severity was seen in rats treated at age 1, 6, and 18 mo. Regenerative activity was more widespread in young animals than in older individuals.

- 8158 EXPERIMENTAL COMPARATIVE STUDIES OF THE EFFECT OF PREDNISONE ON ACUTE LIVER DAMAGE, EMPLOYING VARIOUS METHODS OF CORTICOID ADMINISTRATION. (Ger.) Tessmann, D. (U. Rostock, Germany) and P. F. Ziegler. Zschr. Ges. Inn. Med. 21(2):45-48, 1966.

In adult rats, simultaneous admin. of prednisolone by various routes (5 mg, p.o. or i.v.; or 5-15 mg, i.m.) with an acutely toxic, intragastric dose of CCl_4 intensified the necrotic process in the liver to a marked degree, while retarding resorption significantly. The most marked effects were observed in animals receiving prednisolone p.o. Despite the considerable increase of liver damage, the percentage mortality among prednisolone-treated animals, prior to sacrifice at 72 hr., was decreased significantly.

- 8159 EFFECT OF EXTRACT PREPARED FROM REGENERATING LIVER ON LIVER REGENERATION IN RATS POISONED WITH CARBON TETRACHLORIDE. (Hun.) Balázs, M. (Inst. Postgrad. Med. Train., Hungary), I. Magyar, R. Richter and J. Valu. Kiserl. Orvostud. 18(1):79-86, 1966.

Rats were treated for 7 mo. with CCl_4 , after which the toxic agent was suspended and liver extract started. The effect on liver regeneration of extracts from healthy rat livers, untreated or exposed to CCl_4 for 48 hr. after autolysis, and from livers of rats treated with CCl_4 for 3 mo. was compared. At 10 mo., none of the livers from the 7 untreated controls showed complete or significant regeneration, as against 13 of 16 livers from rats treated with healthy liver extract, 7 of 14 of those treated with liver extracts briefly exposed to the poison, and 16 of 17 of those treated with extracts from livers damaged by CCl_4 treatment for 3 mo. Evidence of residual liver-cell damage in the form of hydropic degeneration was also least pronounced in the last group.

- 8160 EXPERIMENTAL THERAPY OF LIVER DISEASES PRODUCED BY INDUSTRIAL POISONS. (Rus.) Arziaeva, E. Ia. (Inst. Indust. Hyg., Gorkii, USSR). Gig. Trud. Prof. Zabol. 10(2):33-37, 1966.

In adult male albino mice and rats liver lesions were induced by CCl_4 (0.5 ml/100 g body wt., s.c.), trinitrotoluene (1; 0.8 g/kg, intragastrically) and sodium selenite (11; 4 mg/kg, intragastrically). Treatment with pyrimidines (200 mg/kg inj.; uracil methacil (methylthiouracil), isomethacil and 4,6-dihydroxypyrimidine) was initiated 24 hr. after poisoning and continued for the next 10 days. In rats, I increased plasma bilirubin to 0.33 mg% and urobilin in the urine to 2.4 mg% for 20 days. Other liver functions were abnormal for 5-15 days. For 20 days after I, hippuric acid after a sodium benzoate load was less than half normal and hyperglycemic coefficient increased about 40%. Selenite had the least effect on the liver. Prophylactic admin. of isomethacil, methacil and 4,6-dihydroxypyrimidine, and to a lesser extent uracil, reduced the lethality of CCl_4 , I, and the selenite in mice. Methacil, isomethacil and dihydroxypyrimidine improved carbohydrate metabolism, but uracil

LIVER AND BILIARY TRACT

had no effect in I-poisoned rats. In the rats receiving CCl_4 or selenite the blood sugar curve and hyperglycemic curve were normalized 5 days after treatment with the pyrimidines. Pyrimidines improved hepatic ability to metabolize and assimilate lactose and normalized glycogen synthesis in rats poisoned by CCl_4 , I or selenite 7 days earlier. Methacil and isomethacil improved liver function; uracil and dihydroxypyrimidine had lesser effects on the protein synthesizing function of toxic liver. The ratio of serum lipoproteins was normalized by methacil and isomethacil for all three hepatotoxins, but uracil and dihydroxypyrimidine were not as beneficial. The pyrimidines normalized bilirubin and urobilin levels, but uracil was completely ineffective against trinitrotoluene and less effective than the others against I. Prolonged sleep induced by hexanal and thiopental by these hepatotoxins was normalized by methacil, isomethacil and dihydroxypyrimidine, but uracil had no effect. Excretory hepatic function after CCl_4 or selenite poisoning was normalized by the pyrimidines, especially by isomethacil and dihydroxypyrimidine, less by methacil and uracil was ineffective. In trinitrotoluene poisoning, the most effective were methacil and isomethacil; dihydroxypyrimidine and uracil were less effective. Pyrimidine markedly decreased the fatty degeneration of the hepatic cells, central necrosis of the hepatic lobes, and increased glycogen content. After 7 days the morphology appeared normal, especially after treatment with isomethacil. Methacil, isomethacil and 4,6-dihydroxypyrimidine are recommended for the treatment of chemical hepatotoxicity.

- 61 IMPORTANCE OF THYROID HORMONE AND TESTOSTERONE IN THE INDUCTION OF CARCINOMA AND CIRRHOSIS OF THE LIVER IN FEMALE WISTAR RATS INGESTING N-2-FLUORENYLDIACETAMIDE. (E.) Reuber, M. D. (NCI, Bethesda, Md.). J. Nat. Cancer Inst. 36(4):775-781, 1966.

Male Wistar rats were given 0.025% N-2-fluorenyldiacetamide, a hepatocarcinogen, in the diet, and the relationship of the thyroid to the adrenals and to sex and sex hormones in carcinogenesis and cirrhosis of the liver was evaluated. Intact, thyroidectomized, adrenalectomized, castrated, thyroidectomized-castrated, and adrenalectomized-castrated female animals fed the carcinogen-containing diet failed to develop tumors or cirrhosis of the liver. Exogenous thyroid hormone did not induce hepatic carcinomas in any of the animals. Testosterone propionate was not effective when admin. alone to thyroidectomized or thyroidectomized-castrated animals, but when given simultaneously with thyroid hormone, tumors and cirrhosis of the liver did develop in female animals. Thyroid hormone and testosterone propionate are necessary for the induction of carcinomas and cirrhosis of the liver in both male and female rats.

- 62 RELATIONSHIPS BETWEEN RAT HEPATOMAS AND HEPATIC GLYCOLYSIS AND HEXOKINASE ACTIVITY. (Ger.) Sydow, G. (Inst. Cancer Res., German Acad. Sci., Berlin). Zschr. Naturforsch. 21b(3):232-237, 1966.

A comparative study was made of normal rat livers, livers rendered precancerous by admin. of 4-dimethylaminoazobenzene (I) and livers from animals bearing either transplanted or I-induced, primary hepatomas. Tumor transplants were derived from animals in which they had been induced by I or diethylenedinitrosamine (II). Hexokinase activity, glycolysis, glucokinase activity and glycogen content were determined at low, low, high and high, resp., in both normal and precancerous rat livers. In the presence of I-induced, primary hepatomas, they were rated as high, high, low and low, resp. In animals bearing transplanted tumors, including one I-induced ascitic (Zajdela) hepatoma, hexokinase activity and glycolysis were both significantly above normal, but neither glucokinase activity nor glycogen content could be demonstrated. Using glucose as a substrate, the addition of exogenous hexokinase resulted in an increase of lactic acid formation in all tissue supernatants, but with significant differences: 14-20 times for normal or precancerous livers; 5-7 times in the presence of primary or transplanted, solid I-hepatomas; 2-3 times in the presence of II- or I-ascitic-hepatomas. When glucose-6-phosphatase was used as a substrate, instead, a similar, but less marked effect was observed; while addition of adenosine monophosphate with glucose-6-phosphatase as substrate resulted in considerably increased glycolysis. It is concluded that hexokinase can limit glycolysis in liver tissue, but that its action depends upon the extent to which they contain some other enzyme: possibly, phosphofructokinase.

- 8163 EFFECT OF AFLATOXIN ON DNA METABOLISM IN THE COURSE OF COMPENSATORY HYPERTROPHY OF THE LIVER FOLLOWING PARTIAL HEPATECTOMY. (Fr.) De Recondo, A. M. (Norm.-Cancer Cell Res. Ctr., Villejuif/Seine, France), C. Frayssin, C. Lafarge and E. Le Breton. Biochim. Biophys. Acta 119(2):322-330, 1966

Groups of rats which were partially hepatectomized 36 hr. before sacrifice received i.p. inj. of crystalline aflatoxin B₁ at varying intervals after surgery, plus an i.p. inj. of tritiated thymidine admin. 1 hr. before sacrifice. Hepatic conc. of deoxyribonucleic acid remained unchanged, although the uptake of thymidine into the newly synthesized substance was inhibited by 65%, 85% and 95% after 1, 2 and 12 hr., resp. Autoradiography confirmed that the percentage of labeled nuclei remained virtually unchanged, although the grain-count per nucleus was sharply reduced, even when the toxin and precursor were admin. simultaneously 1 hr. before sacrifice. This indicated an abrupt arrest of synthesis by cells which were about to enter into mitosis and beginning to synthesize deoxyribonucleic acid. The activities of deoxyribonuclease I and II were not affected. In studies *in vitro* (using calf-thymus deoxyribonucleic acid as a "primer") all the enzyme systems involved in the synthesis of deoxyribonucleic acid, including the so-called native activating factor, proved to be hyperactive, confirming the conclusion that aflatoxin B₁, like actinomycin D, affected the "primer" molecule directly without accelerating catalytic processes as such.

- 8164 HISTOCHEMICAL ENZYME STUDIES OF RAT LIVER AFTER TREATED AND UNTREATED CARBON TETRACHLORIDE POISONING. (Ger.) Goslar, H. G. (U. Bonn, Germany) K. H. Jaeger, E. Scheithauer and J. Pichotka. Arzneimittelforschung 16(3):359-364, 1966.

The effects of subacute carbon tetrachloride poisoning on rat liver enzymes were studied in untreated animals and in animals receiving protein-free extract of calves' blood for 13 days prior to sacrifice, beginning on day 3 after the final admin. of the poison. In both treated and untreated rats, acid and alkaline phosphatase, adenosine triphosphatase and non-specific α -naphthyl acetate esterase had returned to normal levels within 2 wk. after termination of poisoning. In untreated animals, there was no significant recovery, during this same period, with respect to diphosphopyridine nucleotide diaphorase, lactate dehydrogenase or glucose-6-phosphate dehydrogenase; but in treated animals, the first two showed virtually normal levels of activity in the central lobe of the liver and the third had been essentially normalized throughout the organ. In untreated animals, a continued and progressive, marked decrease of succinic dehydrogenase activity had been evidenced throughout the interval, while treated animals were showing the first evidences of its incipient recovery at the time of sacrifice. The authors conclude that the blood extract accelerated regeneration of the enzymes most directly involved in the production of energy.

- 8165 LONG-TERM ALCOHOL ADMINISTRATION. ITS EFFECTS ON THE ULTRASTRUCTURE AND LIPID CONTENT OF THE RAT LIVER CELL. (E.) Thorpe, M. E. C. (U. New South Wales, Kensington, Australia) and C. D. Shorey. Am. J. Path. 48(4):557-577, 1966.

Rats fed a normal diet with water containing 20% alcohol for 13 mo. showed fine structural changes in the hepatic parenchymal cells after 3 mo. The principal change seen was dilation of the granular endoplasmic reticulum to form lacunae which contained fibrillary material. This change caused minimal cellular disorganization, did not progress to obvious necrosis, and disappeared within 1 mo. after the alcohol diet had been terminated. Parallel liver lipid alterations did not occur; liver triglycerides increased only slightly after 6 mo. Serum triglycerides and albumin levels remained within normal ranges, while serum free fatty acid level diminished after 4 mo. A wt. loss of 7% was seen in the first 1 mo., with a 10% loss thereafter, but there was no increase in the wet liver wt./total body wt. ratio.

- 8166 THE HUMAN LIVER AFTER RADIATION INJURY. A FORM OF VENO-OCCLUSIVE DISEASE (E.) Reed, G. B., Jr. (Stanford U. Sch. Med., Palo Alto, Cal.) and A. J. Cox, Jr. Am. J. Path. 48(4):597-611, 1966.

Liver specimens taken from 12 adults who received irradiation therapy (3000-5000 r

VER AND BILIARY TRACT

the liver over 6 wk. in fractional doses) for metastatic tumors showed a sequential change related to the time lapse since irradiation. Specimens taken 31 days after treatment showed a loose reticulum of delicate fibers among the C in the efferent vein lumens, followed by fusion of these fibers with collagenous structures of the vessel wall, then by development of a relatively compact meshwork of collagenous fiber. Specimens obtained 41-100 days after treatment showed even more severe hyperemia, hepatic cell loss (pronounced near the lobule centers), and the same central vein changes. The hepatic structure showed evidence of returning to normal in specimens obtained 129-324 days after treatment. There was no evidence of pre-existing thrombosis. Scarring of the liver was minimal.

- 67 THE ULTRASTRUCTURE OF FATTY LIVER INDUCED BY PROLONGED ETHANOL INGESTION. (E.) Iseri, O. A. (Boston City Hosp.; Mass.), C. S. Lieber and L. S. Gottlieb. *Am. J. Path.* 48(4):535-555, 1966.

Microscopic examination of livers from rats treated with an "ethanol diet" (36% of the sucrose calories in the basic diet were replaced by ethanol) for up to 42 days showed lipid accumulation which followed the same general zonal distribution as the endoplasmic reticulum changes. The latter changes were evident after 6 days and were characterized by replacement of the elongated profiles by abundant vesicular structures, with or without ribosomes on their surfaces. After 16 days of the ethanol diet, the following mitochondrial changes appeared (and progressed): enlargement with shortening of the cristae, pallor of the matrix, decreased numbers, absence of matrix granules, and appearance of bizarre shapes and intracristal filamental fibrils. Microbodies, lysosomes, and the bile canaliculi were unchanged, while the Golgi zones varied in a way unrelated to duration of diet or lipid accumulation. In the control livers, the granular endoplasmic reticulum of the cells immediately adjacent to the central veins was more irregular than in those cells located further from the veins.

- 68 ULTRA-STRUCTURAL CHANGES IN THE LIVER OF TUMOR-BEARING RATS DURING THE TERMINAL STAGES OF LIFE. (E.) Parry, E. W. (U. Sheffield, England) and F.N. Ghadially. *Cancer* 19(6):821-830, 1966.

The livers of 3 rats with 9:10-dimethyl-1:2-benzanthracene-induced sarcomas (of the c. tissue or uterus) were removed during the terminal stages of life. Under the light microscope, varying degrees of necrosis were seen; there were no obvious circulatory changes or bile duct proliferation, and the necrotic changes seemed to affect only about 25% of the cells. Under the electron microscope, however, the liver cells showed a marked increase in number and size of the lysosomes. These organelles were seen in all stages of transition from normal size and shape to grossly swollen lysosomes, some of which had burst. Other ultrastructural changes included the formation of intermitochondrial bridges and hernias, the appearance of dense bodies in the Golgi vacuoles, and areas of focal cytoplasmic degeneration. It is suggested that material released by bursting of the lysosomes causes liver damage, and that the dense bodies in the hypertrophied Golgi system arise as a result of the demand made on the lysosomal system of the liver of the tumor-bearing animal.

- 69 EFFECT OF p-HYDROXYPROPIOPHENONE ON FIBROSIS INDUCED BY CARBON TETRACHLORIDE IN MICE. (E.) Unakar, N. L. (Brown U., Providence, R. I.). *Am. J. Path.* 48(6):897-919, 1966.

Treatment with p-hydroxypropiophenone (I) inhibited the development of hepatic fibrosis and cirrhosis induced in rats by dimethylaminoazobenzene. I alone had no visible effect upon the liver of mice. In mice fed a semisynthetic diet containing 1% I and treated with carbon tetrachloride (0.1 ml of 40% oil soln., 3 doses/wk. p.o. or s.c.), large numbers of reticulin fibers appeared in the liver even after 4 doses of CCl₄, but few well-developed collagen fibers were noted. In control mice treated with CCl₄ only, the liver showed a large quantity of well-developed collagen but very few reticulin fibers. It is suggested that I interferes with the normal maturation of collagen during the process of fibrogenesis.

Viral Hepatitis

- 8192 PRELIMINARY STATISTICAL EVALUATION OF THE COURSE AND DEVELOPMENT OF 460 CASES OF VIRAL HEPATITIS FOLLOWED FROM THE INITIAL PHASE OF THE DISEASE WITH CLINICAL OBSERVATIONS AND DETERMINATION OF BIOLOGICAL PARAMETERS. (It.) Giusti, G. (U. Naples, Italy), F. Piccinino and L. Cacciatore. Gior. Mal. Infett. 17(12):902-907, 1965.

The clinical course and progression of disease was studied in 460 patients (over 50% between 2-20 yr. old; 60.56% male) with viral hepatitis who had been followed from the onset of disease. Patients had been treated with liver extracts, vitamin B complex, digestive enzymes, special diet, and, in some cases, prednisone. The overall number of cures from 30 to over 120 days after onset of disease was 419 (91.09%) patients; the greatest number of cures (68.92%) occurred within 60 days after the appearance of jaundice; 18.4% cures occurred between days 60-90 of disease; cures were infrequent after 90 days. In 35 patients (7.61%), signs of active disease persisted more than 120 days after the appearance of jaundice. Six deaths (1.3%) occurred, 5 of which were in coma and 1 from bone marrow aplasia. Correlations between clinical course of the disease and various parameters showed the following: earlier cures in patients under 15 yr. old; shorter course in female patients; longer course in patients whose initial bilirubinemia was higher than 10 mg%; longer course in patients with fever before the appearance of jaundice.

- 8193 INVESTIGATION OF THE IMMUNOLOGICAL MECHANISM IN CHRONIC HEPATITIS AND POSTVIRAL HEPATIC CIRRHOSIS. (Fr.) Fodor, O. (3rd Clin. Med., Cluj, Rumania), N. Parau, G. Nicoara and A. Ban. Rev. Int. Hepat. 15(7):1247-1255, 1965.

The presence of circulating anti-liver antibodies was determined by the Ouchterlony gel precipitation, Boyden passive hemagglutination, Steffen antiglobulin consumption, complement fixation, and latex tests in the sera of 50 patients with active chronic hepatitis and 10 patients with postviral cirrhosis. Positive response to hepatic antigen exclusively was seen in 12 of 50 hepatitis and 3 of 10 cirrhosis patients. Positive response to hepatic antigen in addition to positive response to other antigens occurred in 10 of 50 hepatitis and 3 of 10 cirrhosis patients. Positive response to other antigens only occurred in 15 of 50 hepatitis and 2 of 10 cirrhosis patients. Negative response to antigen was observed in 13 of 50 hepatitis and 2 of 10 cirrhosis patients. Signs of splenic hyperfunction (anemia, leukopenia, thrombocytopenia, or pancytopenia) were present in 14 hepatitis patients; in 3 patients the Coombs and hemolysin tests were positive; no lupus cells were present. Sera of animals isoimmunized with hepatic antigen showed cross precipitation reactions with other antigens (kidney, spleen); complement fixation test was positive with hepatic antigen and negative with other antigens; animals isoimmunized with splenic or renal antigen cross reacted with all the other antigens.

- 8194 ATYPICAL ONSET OF VIRAL HEPATITIS. ANALYSIS OF 21 OBSERVATIONS DERIVED FROM AN EPIDEMIC GROUP OF 2,876 CASES. (Fr.) Laverdant, C. (Val-De-Grâce Milit. Hosp., Paris), R. Duriez and E. Lemoine. Rev. Int. Hepat. 15(7):1199-1214, 1965.

Among 2,876 patients hospitalized in North Africa (1961-63) during an epidemic of viral hepatitis (7.03% of total morbidity), 21 patients had an atypical, extra-hepatic, onset of disease. Presenting symptoms were classified as thoracic (2 pericarditis, 3 pleuropulmonary disease), abdominal (3 appendicitis, 1 hepatic colic), neurological (2 polyneuritis, 1 Guillain-Barré syndrome, 1 lymphocytic meningitis), visceral (1 orchiditis, 1 diabetes), and miscellaneous (4 polyarthritides, 1 conjunctivitis, 1 urethritis). The diversity and early appearance of these extra-hepatic initial manifestations suggest a more prominent etiological role of the virus itself, in contrast to the allergic, toxic, or microbial (non-viral) hypotheses usually presented. The epidemiological, clinical, biological, and prognostic similarity observed in 90,000 observations of hepatitis in Algeria seems to disprove a multiple virus hypothesis.

95 ADENOVIRUS IN BLOOD CLOTS FROM CASES OF INFECTIOUS HEPATITIS. (E.)

Hartwell, W. V. (U.S. Public Health Serv., Phoenix, Ariz.), G. J. Love and M. P. Eidenbock. *Science* 152(3727):1390, 1966.

Blood specimens derived from patients with sporadic infectious hepatitis in an acute phase yielded adenovirus Type 5 in 27 of 30 cases, as did all blood specimens derived from 12 immediate family contacts of 2 of the patients. Three of these family contacts developed the disease subsequently. Blood specimens from a matched control group of 70 subjects with no known contact with the disease yielded a virus (also adenovirus Type 5) in only 1 case. Isolation procedures are detailed.

96 SERUM TRANSAMINASE ACTIVITY IN LIVER AND BILIARY TRACT DISEASES. (E.)

Perčič, V. (City Hosp., Subotica, Yugoslavia), S. Stojšić, T. Hegediš and M. Ostrogonac. *Am. J. Gastroent.* 45(5):348-354, 1966.

Serum glutamic-pyruvic (I) or glutamic-oxalacetic transaminase (II) levels (expressed in Wroblewski U) were increased 20-100-fold and over 10-fold above normal, resp., in 90% and 80%, resp., of 290 patients with acute infectious hepatitis. I and II levels were normal (30 and 40 U, resp.) in only 6 and 7 patients, resp. There was a good correlation between elevated I and II levels and elevation of serum bilirubin and alkaline phosphatase. All of the patients with normal thymol flocculation tests (34% of observed cases) showed elevated serum transaminases. Serum transaminase levels decreased as the clinical condition improved. I and II levels were normal in 25 and 17, resp., of 60 patients with chronic hepatitis; the average elevation of the transaminases was much less than in acute hepatitis (above 200 U in 2 and 10 cases, resp.). I was normal in 25 of 65 patients with cirrhosis; II was elevated in all cases, especially during the active phase. Serum I and II levels were elevated in 13 and 9, resp., of 15 patients with primary or metastatic liver carcinoma; these levels were over 100 U in the presence of large liver tumors, elevated alkaline phosphatase, and hyperbilirubinemia. All liver function tests were normal in 10 patients with the posthepatitis syndrome. I and II levels were normal in 37 and 30, resp., of 60 patients with cholelithiasis; elevation of either enzyme above 100 U (6 and 8 patients, resp.) was generally associated with persistent obstructive jaundice and high alkaline phosphatase levels, indicating liver damage.

97 REFLECTIONS ON THE TREATMENT OF VIRAL HEPATITIS. (455 OBSERVATIONS.)

(Fr.) Roux, M. (Maritime Hosp., Toulon, France), A. Fritz, J. Marion, J. Mériaux and W. Antiglio. *J. Med. Bordeaux* 143(4):493-503, 1966.

The results of treatment were evaluated in 455 patients (mostly young men of military service age) with viral hepatitis observed from 1959 or 1961 to 1965. Patients were treated for an av. 3-wk. period with liver extracts, vitamins, antibiotics, and hepatoprotective agents (Group 1; 170 patients) or with cortisone in total doses of 50 mg (Group 2; 285 patients). Response was normal in 389 patients; disappearance of jaundice and improvement of the general condition were similar in both groups. Unfavorable response was observed in 66 (14.5%) patients. Among patients of Group 1, persistence of jaundice occurred in 11 patients (5 for more than 40 days) and recurrence in 4. Among patients of Group 2, persistence of jaundice occurred in 28 patients (20 for more than 40 days), recurrence in 19, progression to chronic hepatitis in 1, progression to cirrhosis in 2, and death due to perforation of duodenal ulcer in 1. Results indicate a higher incidence of persistent jaundice, recurrence, and other chronic progression among corticosteroid-treated patients. The authors no longer recommend their use in the usual forms of viral hepatitis.

98 γ -GLOBULIN IN THE PROPHYLAXIS OF POSTTRANSFUSION HEPATITIS. (E.)

Holland, P. V. (NIH, Bethesda, Md.), R. M. Robinson, A. G. Morrow and P. J. Schmidt. *J.A.M.A.* 196(6):471-474, 1966.

Over a 14-mo. period, 167 adults and children with congenital or acquired cardiac malformations underwent open-heart surgery using whole blood; they were exposed to a total of 4085 U of whole blood, 79% of which had been purchased from commercial sources. Patients receiving blood or blood products 7-180 days before surgery, and all but 1 of the patients who died within the first 180 days postoperatively, were excluded. A randomly selected group of 84 patients received a commercial

γ -globulin preparation (10 ml of 16% soln. i.m.) on the day of operation, followed by another inj. from the same lot (10 ml) about 30 days later; the other 83 patients were untreated and did not receive a placebo. The incidence of icteric hepatitis in the treated and untreated patients was 13% and 7% (11 and 6 cases), resp.; anicteric hepatitis was noted in 3 of the former group and 5 of the latter. The total incidence of hepatitis (over 6-12 mo. of follow-up) was therefore the same in both groups. There was no difference in the relative severity of the disease or in the time of onset; the av. incubation period was less than 50 days. Patients developing icteric hepatitis were significantly older (av. 40.6 yr.) than those who did not (av. 30.3 yr.) and had received significantly larger amounts of blood (av. 29.1 and 23.9 U, resp.). This lack of protective effect may have resulted from washing out of the admin. γ -globulin during the massive transfusion of open-heart surgery.

- 8199 EXPERIENCE WITH THE USE OF GAMMA GLOBULIN IN THE PROPHYLAXIS OF INFECTIOUS HEPATITIS. (It.) Suzzi Valli, E. (Dept. Hyg.-Health, Milan, Italy). Gior. Mal. Infett. 17(12)(Suppl.):969-971, 1965.

In a total of 6,365 children, young adults, and personnel (age 0-20 yr. old) belonging to various institutions, camps, schools, and family groups receiving prophylactic treatment with gamma globulin (0.02 ml/kg children; 0.03-0.04 ml/kg adults), infectious hepatitis developed in only 2 children (age 7 and 5 yr. old) after 12 and 5 days, resp. In both cases, the children were probably in the late incubation period of the disease, since another group member had already shown evidence of hepatitis. Observation periods ranged from 4-8 mo. in all groups. Gamma globulin was admin. in each group after the development of hepatitis in other group members. It is concluded that gamma globulin treatment is the most effective method of hepatitis prophylaxis.

- 8200 STATISTICAL INVESTIGATION OF THE INCIDENCE OF HOSPITALIZATION FOR ACUTE HEPATITIS, PROBABLY VIRAL, IN THE CIVIL HOSPITAL OF PADUA DURING THE DECADE 1955-1964. (It.) Coceani, L. (U. Padua, Italy), P. Del Guercio, L. Okolicsanyi and L. A. Scuro. Gior. Mal. Infett. 17(12):862-868, 1965.

The incidence of hepatic disease at the Civil Hospital of Padua for the period 1955-64 was 3,535 of 91,740 hospitalized patients. Among these, 1,364 had acute hepatitis of probable viral origin, the incidence being higher in the 1960-64 period (857; 1.69%) than in the 1955-59 period (507; 1.23%). Only 7 cases were diagnosed as post-transfusional serum hepatitis. There was no significant difference in sex distribution, but incidence was highest (416 of 1,364; 30.49%) in the less than 10-year-old group. Approx. 50% of cases (653) occurred in the 1-20-year-old group. Incidence was highest in the spring and summer for the 1955-59 series and in summer and fall for the 1960-64 period. The av. period of hospitalization was 29.13 days in the earlier series and 27.16 days in the later series. Improvement or cure was seen in 482 (93.2%) patients of the early series and 834 (97.3%) of the late series; stabilization of disease occurred in 15 and 12 patients, resp. Mortality was higher in the early series (0.81%) than in the late series (0.23%). Hepatitis was associated with pregnancy in 10, diabetes in 24, gastroduodenal ulcer in 15, and heart disease in 26 patients.

- 8201 VIRAL HEPATITIS AND PREGNANCY, INCIDENCE AND RECIPROCAL INFLUENCE. (Ger.) Dörfler, R. (St. Georg District Hosp., Leipzig, Germany) and A. Voigt. Munchen. Med. Wschr. 108(19):1042-1047, 1966.

Among 1734 adult women with infectious hepatitis, only 5% were pregnant. There was no evidence that the disease affected the course of the pregnancy unfavorably, or that the pregnancy had an unfavorable effect on the course of the disease. Although the possibility of unfavorable effect on the infant in utero is not excluded, such an effect was not evidenced in the group.

- 8202 THE CORRELATION BETWEEN TOTAL SERUM BILIRUBIN AND AGE IN CHILDREN WITH INFECTIOUS HEPATITIS. (Ger.) Lange, F. C. (U. Würzburg, Germany) and J. Stroder. Klin. Wschr. 44(9):493-499, 1966.

In a group of children (none under 1 yr. of age or over 14) hospitalized for infectious hepatitis, a statistically significant correlation was found between the

increase of total serum bilirubin during the first 12 days of illness and the increased age of the child. When the children were separated into subgroups in terms of point of origin, it was found that the correlation held for children living in the same town, while no significant correlation could be demonstrated for the subgroup which came from a number of different towns and cities.

- 203 HISTIDASE AND UROCANASE ACTIVITIES OF LIVER AND PLASMA. CORRELATIONS BETWEEN TISSUE ENZYME LEVELS AND PLASMATIC INCREASES DURING HUMAN AND MOUSE VIRAL HEPATITIS. (E.) Coltorti, M. (U. Naples, Italy), A. Di Simone and G. Budillon. *Clin. Chim. Acta* 13(5):568-573, 1966.

At equal substrate conc., histidase and urocanase activities in human liver were about 5 and 3.5 times lower, resp., than the corresponding activities in mouse liver. Urocanase activity was higher than that of histidase in both species. The apparent K_m values for mouse and human histidase in liver were 2.71×10^{-4} M and 4.83×10^{-3} M, resp.; corresponding values for urocanase were 3.19×10^{-6} M and 2.18×10^{-6} M, resp. In mice infected with MHV-3 hepatitis virus, the activities of both enzymes were reduced about 50% after 36 hr.; both enzymes appeared in the plasma during this time, but the elevation of plasma histidase was quantitatively greater than that of urocanase (a 10-fold increase after 36 and 48 hr.). Urocanase was absent from the plasma of normal mice, but appeared in the blood during the hepatocellular necrosis phase. The levels of both enzymes in the plasma of patients with viral hepatitis were very low in the acute phases of the disease; there was no constant relationship between plasma enzyme levels and the presence of hepatocellular necrosis (determined by serum transaminase levels).

- 204 CONSIDERATIONS ON THE NATURE OF CEREBRAL LESIONS IN EPIDEMIC HEPATITIS. (Fr.) Gavrilă, I. (Clin. Infect. Dis., Cluj, Rumania), A. Rosenberg and C. Pirvu. *J. Med. Lyon* 47(1099):859-864, 1966.

Cerebral changes were studied at autopsy in 13 patients with infectious hepatitis and neuropsychiatric manifestations of severe hepatic insufficiency. Lesions were most pronounced in the capillaries of the choroid plexus and in the cerebral pre-capillaries and consisted of thickening and edematous dissociation of the capillary wall and accumulation of periodic acid-Schiff-positive material causing capillary occlusion in some cases. Lesions were similar but less severe in the subarachnoid spaces and Pacchionian bodies. In the cerebral perivascular spaces, fragmentation and ameboid-Alzheimer changes were observed in the neuroglia in addition to edema, hemorrhage, and thickening. The role of increased capillary permeability and metabolic glial changes as contributing factors to the appearance of brain lesions in hepatic insufficiency is discussed.

- 205 EXPERIENCE IN GAMMA-GLOBULIN PROPHYLAXIS OF EPIDEMIC HEPATITIS. (Rus.) Faierstein, S. G., T. M. Safonova, R. N. Gavrute, V. A. Dolgova, N. A. Belicheva, B. M. Spektor, A. N. Krylova, E. V. Pogostina, L. L. Kudimova, P. A. Chernomorskaia, V. K. Cherksova, N. S. Tischenko, M. I. Uvarova, E. A. Savelieva, B. V. Berelov, L. M. Gubina, A. O. Grigorian and E. I. Omelchenko. *Zhur. Mikrobiol.* 43(3):117-121, 1966.

In Moscow and its regions a wide field trial of gamma-globulin (dose 1.0, 1.5 or 2.0 ml) was carried out during the pre-epidemic season for the prophylaxis of epidemic hepatitis (21,735 preschool and schoolchildren; vaccinated = 9,451, controls = 12,284; 1962-1963). It proved to be sufficiently effective for a period of 5-6 mo. from the beginning of admin., acquiring important practical significance in the control of epidemic hepatitis. In the first field trial (lasting 5 mo.) the epidemic hepatitis morbidity index in the group of vaccinated children was 3.7 per 10,000, and in the group of nonvaccinated--19.7. The efficacy index was 5.3. In the second field trial there were no infections in the group of vaccinated children for the first 6 observation mo.; in the nonvaccinated group the morbidity index was 24.8 per 10,000. The rise of epidemic hepatitis morbidity in the experimental group 5 to 6 mo. from the beginning of the treatment indicated the loss of the prophylactic effect. An analysis of the monthly epidemic hepatitis morbidity confirmed the necessity of the closest possible approach of the gamma-globulin admin. period

to the start of the epidemic rise. The prophylactic effect due to different gamma globulin doses given to preschool (aged 3 to 7 yr.) and schoolchildren (aged 8 to 14 yr.) was the same, thus offering a possibility of recommending prophylactic gamma globulin doses not exceeding 1.5 ml.

- 8206 IMMUNOELECTROPHORETIC PATTERN OF SERUM IN INFECTIOUS HEPATITIS. (E.) Ogunbi, O. (U. Lagos Sch. Med., Nigeria). W. Afr. Med. J. 15(2):67-69, 1966.

Serum immunoelectrophoretic studies of 31 patients with infectious hepatitis and 2 patients with other hepatic or non-hepatic diseases indicated that this technic is essentially unsatisfactory from the point of view of primary or differential diagnosis.

- 8207 POSSIBLE CORRELATION BETWEEN VIRUS PARTICLE SIZE AND ACTIVITY OF ANTIVIRAL AGENTS. (E.) Bauer, D. J. (Wellcome Lab. Trop. Med., Beckenham, Kent, England). Nature (London) 209(5023):639-640, 1966.

The relationship between the size of virus particles and the activity of chemotherapeutic agents has been investigated. The theoretical linear relationship between minimal effective conc. of an antiviral compound and virus particle diameter has been graphically illustrated. Points representing the activities of known antiviral compounds against the relevant viruses were determined, and the distance of a point from the line taken as a measure of the efficiency of the compound, which can be defined in numerical terms as the ratio of the theoretical and actual inhibitory conc. expressed as a percentage. For viruses against which no effective antiviral agent has yet been found, the predicted minimal inhibitory conc. (mg/lit) has been transformed to the equivalent dose in g for an adult weighing 70 kg. For the infectious hepatitis virus (diameter $\approx 15 \mu$), the minimal inhibitory conc. was 73.3 mg/liter and the equivalent adult dose was 5,100 mg. To allow for deficiencies in metabolism, absorption, and excretion, the theoretical dose would have to be multiplied several fold. In the case of small viruses, the revised dose would still be within reasonable limits, but, in the case of infectious hepatitis, dosage would be beyond the limits of practicality.

- 8208 SPECIFIC ASPECTS OF RENAL FUNCTION IN INFECTIOUS HEPATITIS AND OBSTRUCTIVE JAUNDICE. (Ger.) Dittrich, P. (U. Innsbruck, Austria). Klin. Wschr. 44(8):441-446, 1966.

In 30 adolescent and adult patients with acute infectious hepatitis, inulin and para-aminohippuric acid (I) clearance were significantly below normal levels, while the max. rates of tubular transport of I and glucose were significantly elevated. No correlation could be established between any of these values and those for serum bilirubin or serum glutamic-oxaloacetic transaminase, both of which were markedly increased above normal. In 10 adult patients with obstructive jaundice (6 of 10 cholelithic), all 4 functions were significantly decreased as compared to normal controls. In this group, a positive correlation was established between values for inulin clearance and those for serum bilirubin and alkaline phosphatase, both of which were markedly increased; between values for I clearance and those for serum bilirubin.

- 8209 AUTOIMMUNE HEPATITIS. IMMUNOFLOUORESCENCE REACTIONS WITH CYTOPLASM OF SMOOTH MUSCLE AND RENAL GLOMERULAR CELLS. (E.) Whittingham, S. (Royal Melbourne Hosp., Australia), I. R. Mackay and J. Irwin. Lancet 1(7451):1333-1335, 1966.

Smooth muscle antibody was demonstrated by immunofluorescence (Weller-Coons technique) in sera of 28 (82%) of 34 patients with lupoid hepatitis and in 9 (48%) of 19 patients with active chronic hepatitis, but in none of 6 patients with primary biliary cirrhosis or 20 patients with systemic lupus erythematosus. Twenty-five sera which contained smooth muscle antibody also reacted with the cytoplasm of cells of the renal glomerulus, this probably being the first example of a spontaneously occurring antiglomerular antibody. This antibody was demonstrated in the serum of a patient with autoimmune lupoid hepatitis who had membranous glomerulonephritis and whose glomeruli contained γ -globulin. The reactivity of the glomerular antibody could

account for the mild membranous glomerular lesions occasionally demonstrated in cases of chronic hepatitis. It is suggested that globulin in the glomerulus is deposited as a result of a reaction in situ in autoimmune hepatitis, while in systemic lupus erythematosus it is part of an antigen-antibody complex formed remotely and lodged accidentally in the glomerulus.

Cirrhosis

- 236 SANDOR'S RETICULOENDOTHELIAL BODIES IN CIRRHOSIS OF THE LIVER. COMPARISON WITH OTHER DIAGNOSTIC TESTS. (Fr.) Boquien, Y. (U. Nantes Sch. Med. Pharm., France), S. Bernard, C. Blain and L. Le Bodic. Sem. Hop. Paris 42(22):1373-1377, 1966.

The presence of Sandor's reticuloendothelial bodies (euglobulin precipitation as a function of pH) in the diagnosis of cirrhosis was revealed by the Adner-Vargues method using a Technicon analyzer in 100 of 500 patients examined. Cirrhosis was confirmed in these patients by the usual diagnostic methods (serum enzymes, peritoneoscopy, liver puncture biopsy). The authors classified results into 4 groups: (I; 21 patients) marked decrease in α -euglobulins; (II; 32 patients) moderate decrease of α -euglobulins; (III; 21 patients) increase in β - and γ -globulins; (IV; 26 patients) atypical modifications of globulin fractions. Comparison of this method with electrophoretic findings showed practically no correlation with α -globulin fractions but some correlation with β - and γ -globulin fractions. With the exception of Group IV, comparison of this method with liver flocculation tests (Gros; thymol turbidity; cephalin-cholesterol) showed the latter to be less sensitive (positive response in only 19, 34, and 38%); greater correlation was seen (except for Group IV) with determinations of serum albumin and prothrombin levels. Results indicate that this test is a valuable adjunct to various laboratory methods of diagnosis of cirrhosis. Studies are underway to determine if the test is of value in the prognosis of cirrhosis.

- 237 THE TOLBUTAMIDE TEST IN HEPATIC CIRRHOSIS. (Fr.) Meeroff, M. (Gregorio Araoz Alfaro Polyclin., Buenos Aires, Argentina) and I. Ruchelsman. Rev. Int. Hepat. 15(7):1257-1271, 1965.

Blood glucose curves were studied in 30 patients (24 with cirrhosis of alcoholic origin) 20-240 min. after i.v. admin. of 1 g of tolbutamide (Unger-Madison test). In 17 of 24 (70%) patients with cirrhosis, blood glucose curves were characteristic of cirrhosis and showed a 30% decrease with respect to base values (55% in some cases) within 20-40 min. and slow return to normal values (2 hr. or more). In the other 7 cirrhosis patients, curves were atypical and irregular, with values less than 30% in 6 of 7 and almost immediate return to base values. In 3 patients with cirrhosis and diabetes, curves were only slightly reduced in 2 and normal in 1. Curves remained practically normal in 2 chronic alcoholic patients without liver damage.

- 238 THE EFFECT OF PORTACAVAL ANASTOMOSIS ON FREE SERUM AMINO ACIDS AND BLOOD AMMONIA FOLLOWING PERORAL ADMINISTRATION OF PROTEIN TO A PATIENT WITH CIRRHOSIS OF THE LIVER. (Ger.) Knauff, H. G. (U. Marburg, Germany), H. Hamelmann, D. Seybold and A. Kanters. Klin. Wschr. 44(3):147-154, 1966.

In cirrhotic patients with portacaval anastomoses, fasting serum levels of glutamine, glutamic acid, methionine, phenylalanine, threonine, tyrosine and ammonia were significantly higher than in normal controls; those of glutamine, methionine, phenylalanine and ammonia were also significantly higher than in non-operated cirrhotics. In both groups, serum levels of alanine, arginine, glutamine, histidine, isoleucine, leucine, lysine, methionine, ornithine, phenylalanine, proline, serine, threonine, tyrosine, valine, total alpha-amino-nitrogens and ammonia showed a marked increase as compared to controls, but without significant differences as concerned the groups, within 2 hr. after feeding protein, 1 g/kg, in the form of an aqueous suspension of powder containing proteins derived from cow's milk. Although large amounts of glutamic and aspartic acid were contained in the protein meal, serum levels of these substances did not increase, indicating their involvement in ammonia binding as confirmed by their increased appearance in the plasma in the form of amides. Thus, although serum conc. of ammonia correlates only loosely with that of glutamine, methionine or tyrosine, determinations of free serum glutamine after stress-feeding of protein can provide a better index of the degree of peripheral binding of ammonia than that provided by determinations of blood ammonia levels, and can indicate more reliably whether a portacaval anastomosis should be considered.

- 8239 BEHAVIOR OF VARIOUS SERUM ENZYMES IN THE COURSE OF ACTIVE HEPATIC CIRRHOSIS (It.) De Battisti, C. (U. Modena, Italy), F. Manenti, N. Carulli and L. Spanio. Clinica (Bologna) 25(5):387-392, 1966.

Results of serum enzyme determinations were compared in 26 patients with cirrhosis mainly of alcoholic origin. The percentage of abnormal response was as follows: 89% of 210 serum glutamic-oxalacetic transaminase determinations; 31% of 190 serum glutamic-pyruvic transaminase; 34% of 154 serum aldolase; 32% of 100 sorbital dehydrogenase; 16% of 100 lactic dehydrogenase; 53% of 135 alkaline phosphatase; 39% of 120 leucine aminopeptidase. Results suggest that serum transaminase levels (even more so than ornithine carbamoyl transferase levels) are the most sensitive tests for the evaluation of cellular (if not specifically hepatic) lysis, whereas alkaline phosphatase and leucine aminopeptidase levels are usually good indicators of cholestasis.

- 8240 COMPARISON OF FREE PORTAL PRESSURE AND WEDGED SUPRAHEPATIC PRESSURE IN NINE CASES OF CIRRHOSIS. PRELIMINARY STUDY. (Fr.) Viallet, A. (Saint-Luc Hosp., Montreal, Canada), P. Lavoie, A. Légaré, J. Bernier, P. Montgrain and J. G. Joly. Un. Med. Canada 95(5):519-523, 1966.

Portal pressure was measured by combined umbilico-portal and suprahepatic catheterization in 9 patients with cirrhosis. Basal values of wedged suprahepatic venous pressure and free portal pressure were compared. A positive pressure gradient between free and wedged pressure was observed in all patients. In 2 patients, hypertension of the inferior vena cava was observed due to stenosis of the blood vessel in its retrohepatic supradiaphragmatic portion. In 7 of 9 patients, the gradient between the 2 pressures was equal or inferior to 1 mm Hg. The av. wedged suprahepatic venous pressure and free portal pressure was 21.6 and 21.2 mm Hg, resp. The correlation between the 2 values is highly significant ($r = 0.837$). If this identity between the 2 pressures is confirmed, many prior hypotheses regarding the physiopathology of portal hypertension in cirrhosis will have to be revised.

- 8241 SIGNIFICANCE OF HEMATOCHYLIA IN LAENNEC'S CIRRHOSIS. (E.) Denney, M. K. (Wayne State U. Sch. Med., Detroit, Mich.), C. E. Lucas and R. C. Read. Arch. Surg. (Chicago) 92(5):657-663, 1966.

The thoracic duct was cannulated in 19 patients with cirrhosis of the liver. Seven showed hematochylia (100,000 to 1,100,000 RBC/cubic mm) and long standing symptomatology, esophageal varices rather than prominent ascites, high thoracic duct pressure, and a hyperkinetic circulation. Hematochylia was occasionally non-uniform, tended to increase with drainage, remained unaffected by portacaval decompression, and was associated with clear hepatoportal lymphatics. The therapeutic effect of thoracic duct drainage was disappointing in ascites but more promising in the initial management of bleeding varices. Thoracic duct pressure could not be attributed to obstruction at the subclavian junction; it related more to hematochylia than flow rate. Dogs with chronic aortocaval fistulae developed a similar degree of hematochylia. This phenomenon could not be produced by supradiaphragmatic caval constriction. Contamination of lymph by red cells in these animals was shown to be related to peripheral venolymphatic communications within or draining into regional lymph nodes. Results are considered inconsistent with the hypothesis that hematochylia in patients with liver disease results from leakage of red cells into the perisinusoidal spaces of Disse. It is believed that arteriovenous shunting plays a significant role in the hemodynamic alterations found in cirrhosis.

- 8242 HEMODYNAMIC CHANGES WITH CIRRHOSIS OF THE LIVER: CONTROL OF ARTERIOVENOUS SHUNTS DURING OPERATION FOR ESOPHAGEAL VARICES. (E.) Johnson, G., Jr. (U. North Carolina Sch. Med., Chapel Hill), C. H. Dart, Jr., R. M. Peters and J. A. Macfie. Ann. Surg. 163(5):692-703, 1966.

Hemodynamic studies in 37 patients with cirrhosis and 34 control patients revealed an increase in cardiac output, blood vol., stroke work, and systolic ejection rate, and a decrease in peripheral resistance in patients with cirrhosis. Findings are similar to those found in patients with systemic arteriovenous fistula and suggest

the presence of multiple arteriovenous fistulas in patients with cirrhosis. A series of 51 patients (34 men and 17 women; 25 between 30-49 yr. old) were subjected to surgery for removal of as many arteriovenous shunts as possible and to decrease arterial flow into the portal system. Operative mortality in relation to type of surgery was 1 death among 5 subjected to splenectomy alone; 12 of 26 subjected to splenectomy and ligation of gastric blood supply; 9 of 20 subjected to splenectomy, ligation of gastric blood supply, and plication of esophageal varices. Twenty-seven (53%) operations were performed as emergencies to control bleeding. Five-yr. survival, excluding postoperative mortality, was 75%. An unusual number of poor-risk patients may have attributed to a high operative mortality. This type of surgery is recommended for the treatment of esophageal varices.

- 3243 COMPLICATIONS OF DIURETIC THERAPY IN HEPATIC CIRRHOSIS. (E.) Sherlock, S. (Free Hosp., London, W.C.1), B. Senewiratne, A. Scott and J. G. Walker. Lancet 1(7446):1049-1053, 1966.

Control of ascites was achieved in 106 of 112 patients with ascites due to cirrhosis of the liver after treatment with a low-sodium diet and various diuretics (chlorothiazide or frusemide, each with and without spironolactone, or ethacrynic acid). A serum electrolyte disturbance developed in 84 (75%) patients. This was profound in 29 patients; 16 of these patients died within 3 mo. Hypokalemia developed in 43 patients; the incidence was lowest with use of spironolactone and chlorothiazide. Hyponatremia was noted in 46 patients; incidence was about the same with all of the diuretics. Azotemia, which developed in 38 patients, was more frequent after pronounced diuresis following the use of frusemide or ethacrynic acid. Hepatic encephalopathy was seen in 33 patients, particularly after ethacrynic acid therapy; it was related to the severity of the underlying cirrhosis, a general electrolyte disturbance or a very brisk diuresis; hypokalemia was not closely associated with it.

- 3244 ASSOCIATION OF CORTICOSTEROIDS, SPIROLACTONE, SALINE DIURETICS, AND MANNITOL IN A SPECIAL TREATMENT REGIMEN FOR CIRRHOTIC ASCITES. (Fr.) Colucci, C. F. (Cardarelli Hosp., Naples, Italy). Schweiz. Med. Wschr. 96(20):660-665, 1966.

Results of the use of a new regimen are reported in the treatment of 25 patients (18 men and 7 women; age 42-66 yr.) with cirrhosis and ascites which failed to respond to previous treatment. In the first period, treatment consisted of beta-methasone (3.6-4.8 mg/day) alone or in combination with prednisone (30-40 mg/day) or triamcinolone (24-32 mg/day) for 8 days; 5 of 25 patients showed limited response, a moderate diuretic effect appearing by day 4-5. In the second period, spiro lactone was admin. (150-200 mg/day) in combination with corticosteroids for 8 days; 7 patients showed a moderate diuretic effect after 4-6 days; no significant change in blood or urinary potassium levels was observed. When small-to-medium doses of hydrochlorothiazide (50-75 mg), chlorthalidone (100-300 mg), or furosemide (40-80 mg) were added (third period), good diuretic response (2,000-3,000 ml/24 hr.) and wt. loss were observed in 20 of 25 patients. Upon subsequent addition (fourth period) of triamterene (100-200 mg), the diuretic effect observed in the 20 previously described patients was increased, while the 5 who had failed to respond or who had responded slightly to the previous regimen showed good response. In practically all cases, regression of ascites was observed by days 10-12 of the fourth period and 1 mo. after beginning of treatment. After 9-15 mo. of observation, 19 of 25 patients were without ascites or edema and in satisfactory general condition. No side effects were observed from long-term use of the various diuretics. Mortality was 24% (6 patients); 3 died from gastrointestinal hemorrhage at 2, 7, and 13 mo.; 2 died in hepatic coma at 6 and 10 mo.; 1 died from recurrence of ascites at mo. 13.

- 3245 CONSIDERATIONS ON THE PROLONGED USE OF SPIRONOLACTONES IN THE COURSE OF HEPATIC CIRRHOSIS. (Fr.) Muller, M. B. (Saint-Etienne Hosp., Lyon, France) and D. David. J. Med. Lyon 47(1099):831-837, 1966.

In 21 patients (17 men and 4 women) treated with aldactone (1-2 tablets/day for 5 mo. to 3 yr.) for cirrhosis with marked ascites and edema, excellent response (no

persistence of edema) occurred in 9, while 12 others showed persistence of slight edema. In most cases, ascites reappeared after suspension of treatment and regressed when treatment was resumed. Treatment was suspended in 6 patients, 2 of whom because of vertigo (the only side effects noted) and 4 because of regression of ascites. Aldactone was admin. alone in 9 patients and in association with prednisone (1-2 tablets/day) in 6 or saline diuretics in 5. The authors recommend prolonged treatment with spironolactones in combination with corticosteroids or diuretics for the effective management of ascites due to cirrhosis.

- 8246 CHANGES IN COAGULATION FACTORS UNDER PROLONGED TREATMENT WITH ANTICOAGULANT AND IN PATIENTS WITH CIRRHOSIS OF THE LIVER. (Ger.) Nowicki, L. (U. Wurzburg, Germany), K. W. Schneider and M. Reimers. Blut 13(1):36-44, 1966.

Coagulation factors were determined in patients with a history of myocardial infarct and prolonged medication with dicumarol derivatives, patients with cirrhosis of the liver and a group of normal controls. The medicated group showed decreased activity of Factors II, VII, IX and X, although not to a statistically significant degree. The cirrhotic group showed similar, but somewhat less marked changes with respect to all four. Contrary to the common belief that anticoagulant therapy does not affect the level of extra-hepatically produced antihemophilic globulin, Factor VIII was also reduced in the medicated group, as was Factor V. Both VIII and V were even more sharply reduced in cirrhotic patients. The medicated group showed no decrease of fibrinogen level; the cirrhotic group, a sharp decrease. Thrombocyte Factor 3 was normal in the medicated group; showed diminished activity in 17 of 28 cirrhotics. Antithrombin II was normal in the medicated group, decreased in cirrhotics. Antithrombin III was increased in the medicated group, considerably decreased in decompensated cirrhotics but increased in cirrhotics with cholangie. In both medicated and cirrhotic patients, the streptokinase resistance test was statistically significantly lower than it was in normal controls.

- 8247 TREATMENT OF CHRONIC PORTAL-SYSTEMIC ENCEPHALOPATHY WITH LACTULOSE. (E.) Bircher, H. (U. Zurich Canton Hosp., Switzerland), J. Müller, P. Guggenheim and U. P. Haemmerli. Lancet 1(7443):890-893, 1966.

The effects of lactulose (Duphalac; 45-95 g/day p.o. for several treatment periods of 1 wk. each) were compared to those of protein restriction (40 or 70 g/day), neomycin (4-8 g/day), and sorbitol in the treatment of a 52-year-old (Case 1) and 55-year-old (Case 2) man with chronic portasystemic encephalopathy. Effective control of neuropsychiatric symptoms was obtained with protein restriction and neomycin as well as with protein restriction and lactulose (without neomycin). Lactulose and increased protein intake was well tolerated without mental or neurological deterioration. The permanent spastic paraplegia of Case 1 was not improved by either neomycin or lactulose. Lowest blood ammonia levels and least abnormal electroencephalographic changes occurred in Case 1 while on neomycin, but his clinical status was no different from that observed with lactulose. In Case 2, lactulose appeared to be slightly more effective in improving blood ammonia levels and electroencephalographic changes. During lactulose treatment, both patients complained initially of intestinal bloating and flatulence. Fecal pH decreased from the normal value of 7 to values between 4 and 5 in 3-4 days with lactulose. Its action in preventing hepatic coma is presumably due to bacterial changes caused by lowered fecal pH, resulting in a decrease in the production of toxic nitrogenous compounds in the colon.

- 8248 ELEVATION OF THE PRESSURE IN THE ABDOMINAL INFERIOR VENA CAVA AS A CAUSE OF A HEPATORENAL SYNDROME IN CIRRHOSIS. (E.) Mullane, J. F. (New York State U., Downstate Med. Ctr., Brooklyn) and M. L. Gliedman. Surgery 59(6):1135-1146, 1966.

Significant elevations of abdominal inferior vena cava pressure were demonstrated in 23 of 24 ascitic and 45 of 101 anascitic, chronic alcoholics. (In the combined patient group as a whole, atrophic hepatic cirrhosis was demonstrable in 10 cases.) Statistically significant or highly suggestive correlations were shown, as between the presence of such increased pressure and characteristic disturbances of glomerular filtration rate, urinary excretion of sodium, the incidence of abnormal

splenic pulp pressure and the incidence of esophageal varices. In the light of corollary postmortem studies, a major etiologic factor with respect to the increased venous pressure was postulated in terms of thickening and/or lateral growth of the caudate lobe of the liver. The authors also suggest that a redistribution of the renal blood flow, accompanying disruption of the countercurrent multiplication mechanism by the increased pressure within the inferior vena cava, may be responsible for decreased glomerular filtration rates and urinary excretion of sodium in this type of patient.

- 3249 ANATOMIC AND FUNCTIONAL CIRCULATORY CHANGES IN EXPERIMENTAL CIRRHOSIS. (E.) Alpert, L. I. (Royal Free Hosp., London) and S. K. Mitra. Am. J. Path. 48(4):579-595, 1966.

Porto-hepatic venous shunts were traced by means of latex corrosion casts in all cases of nodular cirrhosis which developed in male Wistar rats after exposure to CCl₄ vapors, which produced yield of nodular cirrhosis in 90% of animals within 22 wk. These porto-hepatic venous shunts varied in caliber from 20-100 microns and were found most often in those livers with an internodular fibrous septa having a minimal mean width of 30 microns. The amount of shunting was correlated with the extent of liver function damage, as determined by bilirubin, serum glutamic-pyruvic transaminase, γ -globulin, portal pressure, and hepatic clearance constant measurements. The sinusoidal beds of the nodules in the cirrhotic liver were relatively well-preserved and maintained an intact portal supply. This would explain the marked inverse correlation between the degree of shunt developed and the effective sinusoidal blood flow, and would indicate that these shunts were derived from sinusoids persisting in the fibrous septa. Occasional porto-portal and hepato-hepatic venous shunts were found.

- 3250 FATTY CIRRHOSIS IN THE RAT. XII. THE CIRRHOTIC NODULES. (E.) Zaki, F. G. (U. Minnesota Coll. Med. Sci., Minneapolis). Arch. Path. (Chicago) 81(6):536-543, 1966.

Nutritional cirrhosis developed in male Holtzman rats fed diets containing 20% or 38% fat; prominent nodules of parenchyma and extensive fibrous trabeculae were seen in the liver. The nodules were initially monoacinar types, but as the cirrhosis advanced, they became fatty and enlarged to form multiacinar structures. These nodules received blood from, and developed around, terminal branches of the portal vein. Biliary drainage appeared to be in part by small ducts accompanying the terminal veins. These nodules appeared to originate from irregular periportal regeneration of parenchyma and retained the following characteristics of this area: a certain resistance to CCl₄ and to fat accumulation during the reinstitution of a state of choline deficiency; and development of a mild but diffuse fat accumulation after orotic acid feeding. The nodule cells also were more resistant to common bile duct ligation and partial hepatectomy than the cells of the adjacent acini.

- 3251 SPECIFIC ASPECTS OF RENAL FUNCTION IN CIRRHOSIS OF THE LIVER. (Ger.) Dittrich, P. (U. Innsbruck, Austria). Klin. Wschr. 44(8):438-441, 1966.
In 10 adult patients with anascitic hepatic cirrhosis, inulin and para-aminohippuric acid (I) clearance were moderately, but statistically significantly, below normal levels, while renal blood flow was severely reduced. In 13 adult patients with hepatic cirrhosis and ascites, inulin and I clearance showed a marked, further depression and renal blood flow remained much below normal levels. In both groups of patients, the maximal rate of tubular transport of I was normal; while reabsorption of water (expressed as a percentage of glomerular filtrate during the clearance test) was increased significantly, especially in the presence of ascites.

- 3252 THE PLACE OF DIURETICS IN THE TREATMENT OF CIRRHOTIC ASCITES. (100 OBSERVATIONS.) (Fr.) Levrat, M. (E. Herriot Hosp., Lyon, France) and R. Truchot. Rev. Int. Hepat. 15(7):1159-1185, 1965.

Gallbladder and Biliary Tract Diseases

- 265 JAUNDICE IN PREGNANCY, NOT RELATED TO SPECIFIC INFECTIONS. (Ger.) Farber, N. A. (USSR Acad. Med. Sci., Moscow). Zschr. Ges. Inn. Med. 21(9):265-273, 1966.

Among 964 patients with jaundice occurring during pregnancy, virus hepatitis was demonstrated in 60.1% (with a 1.9% mortality rate); all other forms of jaundice not definitively related to pregnancy, in 11.7% (0.9% mortality rate); the idiopathic jaundice of pregnant women, in 26.0% (0.4% mortality rate). The origin of jaundice could not be established in 2.2%. Among the patients with idiopathic jaundice, approx. half showed functional intrahepatic cholestasis accompanied by severe pruritus lasting 2-20 wk. (av., 6) and usually disappearing immediately postpartum. The jaundice was usually mild. Approx. 1 of 3 showed the same syndrome accompanied by cholelithiasis or nephropathia gravidarum; approx. 1 of 10 showed hyperemesis gravidarum with accompanying liver damage. One of 5 (total) showed some degree of hepatomegaly. Differential diagnosis depended primarily on clinical findings, with pruritus considered a major differentiating factor. Increased serum cholesterol and alkaline phosphatase were seen frequently. One of 4 patients gave a history of previous symptoms suggesting disturbed liver function (most frequently, cholecystitis, cholangitis or cholelithiasis; occasionally gastritis, food poisoning, virus hepatitis or urticaria); an additional one of 3 had developed such symptoms earlier in the course of the same pregnancy; slightly more than half developed such symptoms postpartum. The author concludes that the idiopathic jaundice of pregnant women results from a combination of metabolic, endocrine and mechanical factors creating functional disturbance at a site of temporarily diminished resistance.

- 266 THE ROLE OF CHOLECYSTITIS IN THE PRECIPITATION OF CALCIUM CARBONATE IN HUMAN GALL STONES. (E.) Bogren, H. (U. Goteborg, Sweden). Acta Chir. Scand. 131(4):329-333, 1966.

Gallstones obtained at cholecystectomy from 93 consecutive cases were analyzed for calcium carbonate. The incidence of acute cholecystitis in 28 patients with and 65 patients without calcium carbonate-containing stones was 18% and 32% (5 and 21 cases), resp.; 23 and 44, resp., had primary chronic or no cholecystitis. Biliary stasis, diagnosed by lack of gallbladder filling at cholecystography, icterus, and/or the presence of an obstructive or common duct stone, was present in 36% and 49%, (10 and 22 cases, resp.). These differences were not statistically significant.

- 267 THE ASSOCIATION BETWEEN ABO BLOOD GROUPS AND CHOLELITHIASIS WITH SPECIAL REFERENCE TO BILIARY DISTRESS FOLLOWING CHOLECYSTECTOMY. (E.) Bodvall, B. (U. Goteborg, Sweden) and B. Övergaard. Acta Chir. Scand. 131(4):334-342, 1966.

In 979 patients cholecystectomized for gallstones and followed up after 2 yr., the frequency of blood group A tended to be higher than that of group O, as compared to the relative frequencies of both groups in 2 control groups of randomly selected Swedish men. Frequency of group A was significantly higher in patients under 50 than in older patients. Sex and type of gallbladder disease did not influence the distribution of ABO blood groups. The distribution of Rh factor was the same as in control groups, and was not influenced by age, sex, type of gallbladder disease, or severity of postoperative biliary distress. Absence of postoperative biliary distress was noted almost significantly more frequently in patients with type A blood; as the severity of postoperative distress increased, the frequency of group A fell and that of group O increased significantly. This did not apply, however to the patients with postoperative biliary distress of demonstrable organic causes.

- 268 THE ROLE OF THE COMMON BILE DUCT IN BILIARY DYNAMICS. (E.) Watts, J. McK. (U. California Sch. Med., San Francisco) and J. E. Dunphy. Surg. Gynec. Obstet. 122(6):1207-1218, 1966.

In a series of experiments on the common bile duct in dogs it was found that this structure is not merely a passive conducting tube but, by its own intrinsic activity, contributes to the function of the extrahepatic biliary tract. Pressure recordings in thin isolated segments of the canine common bile duct in vivo have demonstrated

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

independent activity of the duct, both in the unstimulated state and under the influence of cholecystokinin, mecholyl, morphine, pitressin, and upon stimulation of the vagus nerves. These pressure fluctuations were independent and out of phase with those recorded in the gallbladder, sphincter of Oddi and duodenum. Activity of the common bile duct was also demonstrated *in vitro* when the duct was suspended in its longitudinal axis, but no activity was demonstrated during experiments using strips of duct cut in a transverse axis. These *in vitro* findings are in keeping with the chiefly longitudinal orientation of smooth muscle in the duct and the sparsity of circular muscle; it is, therefore, unlikely that true peristalsis of the duct occurs; rather, its movement is primarily one of shortening and lengthening. Cholecystokinin produces contraction of the smooth muscle of the entire extrahepatic biliary tree, including that in the common bile duct. Its effect upon the sphincter of Oddi is primarily an increase in activity which is thought to facilitate the flow of bile from the common duct into the duodenum.

- 8269 THE EFFECT OF BILE DUCT LIGATION, BILE DUCT CANNULATION, AND HYPOTHERMIA ON α -NAPHTHYLISOTHIOCYANATE-INDUCED HYPERBILIRUBINEMIA AND CHOLESTASIS IN RATS. (E.) Roberts, R. J. (U. Iowa, Iowa City) and G. L. Plaa. *Gastroenterology* 50(6):768-774, 1966.

Treatment with α -naphthylisothiocyanate (I; 300 mg/kg p.o.) caused a significant poikilothermic response in rats, together with cessation of bile flow and an increase in serum bilirubin levels within 24 hr. There was a positive correlation (correlation coefficient 0.8; $P < 0.05$) between the response to I and the rectal temperature under hypo- and hyperthermic environmental conditions, but there was a critical body temperature (about 31° C; normal body temperature under these conditions was 36.5° C) below which the cholestatic effect of I decreased. Bile duct ligation reduced the hypothermic response and prevented the cholestatic response to I; bile duct cannulation before I treatment significantly protected against I-induced hyperbilirubinemia, hypothermia, and cholestasis. It is suggested that a biotransformation product of I is responsible for these changes.

- 8270 ON THE STRATIFICATION OF HUMAN BILE AND ITS IMPORTANCE FOR THE SOLUBILITY OF CHOLESTEROL. (E.) Thureborn, E. (U. Goteborg, Sweden). *Gastroenterology* 50(6):775-780, 1966.

Liver bile was collected by drainage from 4 patients up to 9 days after cholecystectomy; 1 had a nonfunctioning gallbladder with histological features of acute cholecystitis, but all patients were afebrile and without clinical signs of infection at the time of bile collection. Mixed stones (not analyzed chemically) were present in the gallbladders of all patients, but no common duct stones were found. Lyophilized bile was extracted and analyzed for lecithin-bile salt, cholesterol, and phospholipids. In an *in vitro* study, hepatic bile collected immediately and up to 3 hr. after interruption of the enterohepatic circulation formed visible layers which were stable for several hr. at room temperature. The upper and lower layers were of different compositions in this study and in another study in which the bile was conc. in a semipermeable cellophane bag maintained for 12 hr. in a soln. of high osmotic action (simulating an atonic gallbladder). The conc. of lecithin-bile salts, cholesterol, and phospholipids were highest in the lower layer and lowest in the upper layer. Cholesterol solubility was very low in the upper layer; the significance of this phenomenon for the precipitation of cholesterol and the formation of gallstones is discussed.

- 8271 SECONDARY EXPLORATION OF THE BILIARY TRACT. (E.) Mongé, J. J. (Duluth Clin., Minn.). *Am. J. Surg.* 111(5):673-677, 1966.

Secondary exploration of the biliary tract was performed in 69 patients (51 females and 18 males; age 27-86 yr.) whose primary surgery had consisted of cholecystectomy (67) or cholecystostomy (2). Operative findings included stones in the common bile duct in 29 patients, cystic duct or gallbladder remnant in 14, stricture of the common bile duct in 5, pancreatitis in 8, cancer of the biliary tract in 4, and negative exploration in 4. Two operative deaths occurred; 1 patient died with a subphrenic abscess after refusing surgical drainage, and the other died with acute hemorrhagic pancreatitis 2 days after a not unusual common bile duct exploration.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

The median period of relief after cholecystectomy was 2 yr. for patients who later proved to have stones in the common bile duct and 5 yr. for those found to have other diseases of the biliary tract. Only 12 patients had the triad of pain, jaundice, and fever, while 23 patients were never jaundiced. The av. follow-up period was 44 mo. Fifty-six of these patients are known to be now doing well. Various means of evaluating the condition of the biliary tract are discussed.

- 3272 STUDIES ON CHOLECYSTOGRAPHY. III. EXPERIMENTAL STUDIES ON RETROGRADE CHOLECYSTOGRAPHY. II. (Jap.) Jibiki, A. (Toho U. Sch. Med., Japan). Nippon Igaku Hoshasen Gakkai Zasshi (Nippon Acta Radiol.) 25(9):1062-1066, 1965.

Retrograde cholecystography was performed using a newly designed duodenal tube with 6 linearly arranged balloons and with 3 tubes connected to each balloon. Anesthesia (4% xylocaine) is admin. prior to swallowing the tube. When the tube reaches the duodenum, 2 egg yolks are admin. After 30-40 min. the duodenum is washed. Balloons 1 and 3 are inflated. Xylocaine (1%) is then admin. through tube 3. An s.c. inj. of At-Sulf (no other details) is admin. After 20-40 min., xylocaine is again admin. through the tube, followed by washing. The contrast soln. (15% Biligrafin, 100 U of Sprase, and 0.5% At-Sulf) is then admin., after which balloon 2 is inflated, producing retrograde flow of the soln. into the bile duct. The author has successfully applied this technic and emphasizes its value in future studies. X-rays are included.

- 3273 CURRENT CONCEPTS IN THE MANAGEMENT OF CONGENITAL BILIARY ATRESIA. (E.) Miller, S. (U. California, Los Angeles), E. W. Fonkalsrud and W. P. Longmire, Jr. Arch. Surg. (Chicago) 92(6):813-817, 1966.

Of 27 infants and children with congenital biliary atresia, 26 underwent a total of 32 operations. All 3 patients with intrahepatic biliary atresia died; 4 patients of 16 with extrahepatic atresia, and 4 of 8 with biliary hypoplasia survived. Biliary-enteric anastomosis of some type was performed in most patients; the most effective seemed to be choledochoduodenostomy or choledochojejunostomy. There were 3 survivors (29.6%) at the time of report; 2 were infants who had survived 3 or 5 mo. One patient underwent 2 choledochoduodenostomies (age 3 mo. and 3.5 yr.) and was alive 6 mo. after the second operation; another patient underwent 3 biliary-enteric anastomoses (age 6 wk., 13 mo., and 4.5 yr.) and was alive 3.5 yr. after the third procedure; another underwent choledochoduodenostomy (age 6 wk.) and the Longmire procedure (age 6 mo.) and was alive 7 yr. after the second operation. The other 3 patients underwent 1 operation each, and were alive after about 5-6 yr. The importance of early diagnosis is emphasized.

- 3274 PANCREATODUODENECTOMY FOR PERIAMPULLARY CARCINOMAS. APPRAISAL OF TWO-STAGE PROCEDURE. (E.) Maki, T. (Tohoku U. Sch. Med., Sendai, Japan), T. Sato and G. Kakizaki. Arch. Surg. (Chicago) 92(6):825-833, 1966.

Of 128 patients with periampullary carcinoma (in or near the ampulla of Vater, head of the pancreas, or intrapancreatic portion of the common bile duct), 57 (44.5%) underwent pancreatoduodenectomy. After development of a 2-stage procedure, the operative mortality fell from 50% to 8%. Causes of death in the 16 patients who died after 1-stage resection were purulent peritonitis due to an impaired pancreatojejunostomy in 8, debilitation with unrelieved jaundice in 6, and massive gastrointestinal hemorrhage in 2. In 109 patients with periampullary and other biliary tract cancers undergoing surgery, the mortality rate was 44%, being especially high (over 50%) in those with a high icteric index (80 or more). The adverse effect of jaundice upon the surgical prognosis was also noted in patients with cholelithiasis. The 2-stage operation, recommended especially for highly jaundiced patients (icteric index 80 or over), consisted of cholecystotomy to relieve jaundice, followed after 3-4 wk. by pancreatoduodenectomy. Patients with lower icteric indices underwent a 1-stage procedure. Of 25 patients undergoing 1-stage (11) or 2-stage (14) resection, 1 patient in each group died. After 2-stage resection, marked relief of jaundice was seen in all patients; anemia was alleviated in most cases, and abnormally high serum transaminases were normalized in about 50% of the group.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

- 8275 EXPERIMENTAL STUDY ON THE MECHANISM OF FORMATION OF CALCIUM CARBONATE STONES. (E.) Maki, T. (Tohoku U. Sch. Med., Sendai, Japan) and N. Suzuki. Tohoku J. Exp. Med. 88(2):181-193, 1966.

Gallstone-like calcium carbonate concretions were produced by supplementing a suspension of precipitated calcium carbonate with an inorganic electrolyte (aluminum chloride or sodium chloride) and an organic polyelectrolyte, followed by rotation in a flask. Among the organic high molecular wt. compounds, the linear polyelectrolytes (sodium alginate, Superfloc 16, Separan 2160, and Konanfloc ZH) had marked coagulating effects, but the global polyelectrolytes (egg albumin) formed much less stable substances, which could often be dispersed by shaking. This study supports the theory that calculi are formed from calcium carbonate (separated from colloidal body fluids) which is coagulated and solidified by the electrostatic effect of electrolytes, the bridging action of high molecular wt. organic substances, and kinetic energy supplied by the organism.

- 8276 FURTHER STUDIES ON THE INFLUENCE OF THYROXINE ON GALLSTONE FORMATION IN HAMSTERS. (E.) Bergman, F. (U. Umea, Sweden) and W. Van Der Linden. Acta Chir. Scand. 131(4):319-328, 1966.

The admin. of tolbutamide or such lipotropic factors as choline chloride, lysine, tryptophan, methionine, and α -tocopherol with or without insulin, or insulin alone, did not prevent the development of fatty liver or gallstones in D-thyroxine-treated hamsters on a 48.2% sucrose diet. However, with the lipotropic factors the incidence of gallstones was slightly less. When hypothyroidism was produced by the admin. of propylthiouracil, hamsters on the same sucrose diet did not develop fatty liver or gallstones, but animals on the same diet plus D-thyroxine did. The gallstone formation and the development of fatty liver brought about by L-thyroxine was comparable to that caused by D-thyroxine.

SUBJECT INDEX

Numbers followed by an asterisk (*) refer to abstracts in the text. Other numbers refer to citations only.

- Abdomen, acute, allergic: 7390
 - book: 7532,7535
 - ileal fibroma: 7710
 - infants and children, rev.: 7418,7420
 - porphyria, in pregnancy: 7432
 - radiologic diagnosis: 7460
- anomalies, surgery: 7370*
- aortic aneurysm: 7366*
- diseases, diagnosis by hepatic scintillation scanning: 8022*
- foreign body: 7443
- reoperation: 7368*,7369*
- trauma, re-laparotomy: 7438,7541
- Abscess, anorectal, surgery: 7851*
- liver: 8019*
- Absorption, amino acid: 7135*,7137*,7140*,7157,7163
- ammonia: 7149*
- bile acids and salts: 7141*,7143*,7234*
- and blood circulation: 7153
- calcium, and vitamin D₃: 7151*
- and Mg, lactose-treated rat: 7133*
- drug: 7125*,7131*,7146*,7147*
- electrolytes: 7128*,7130*
- glucose, effect of vitamin B₁₂: 7161
- imino acid: 7137*
- inhibition by dimethyl sulfoxide: 7157
- intestine, cells: 7124*
- iron: 7139*,7148*,7162
- laboratory tests: 7156
- lipid: 7126*,7144*,7160,7834
- colon: 7138*
- vagotomy: 7760*
- membrane potentials: 7152*
- sugar: 7135*
- triglycerides: 7144*
- triolein: 7143*
- vitamin A, postgastrectomy: 7834
- 3-dehydro-: 7159
- vitamin B₁₂: 7142*
- water: 7128*,7273*
- D-xylose: 7134*,7840
- Acetazolamide, in acute pancreatitis: 7980*
- Achalasia, cardia: 7563
- Adhesions, small intestine: 7700*,7707*
- β-Adrenolytic agents, and alcoholic fatty livers: 8154*
- L-Alanine, transport: 7135*
- Alcoholism, fatty liver, pathogenesis: 8154*
- Alcoholism, fatty liver, ultrastructure: 8167*
- liver ultrastructure: 8165*
- Alkalies, effect on gastric acidity: 7754*
- Amebiasis: 7372*
- children: 8131
- colon mucosa: 7919
- diagnosis: 7359*
- epidemiology, Israel: 7521
- intestine, with malabsorption: 7821*
- liver abscess: 8070
- treatment: 7494,7496,7509
- Ammonia, intoxication: 7149*
- intestinal metabolism, effect of experimental liver damage on: 8151*
- Amphomimetic agents, imidazolin derivative as: 7228*
- α-Amylase, multimolecular complexes: 7216
- secretion, salivary, effect of testosterone: 7185*
- serum, determination after p.o. glucose, pancreatic diseases: 7939*
- Amyloidosis, systemic, diagnosis, rectal biopsy: 7847*
- Anabolic agents, cholestatic effect, liver diseases: 8015*
- toxicity, liver: 8016*
- Analgesic, absorption: 7146*
- Anastomosis, gastroenteric, with gastrectomy, complications, lactose malabsorption: 7817*
- mesenteric-caval vein, and gastric secretion: 7183*
- Anemia, gastric function in: 7175*,7192*
- with malabsorption: 7818*
- Aneurysm, aorta, abdominal: 7366*
- Angiography, selective, in chronic pancreatitis: 7979*
- Anorectal area, abscess, surgery: 7851*
- Anorectal complications, in ulcerative colitis: 7926*
- Anorexia nervosa, concepts: 7450
- Antacid, testing: 7324*
- Antibiotic, absorption: 7147*
- effect on normal intestinal flora: 7082*
- in malabsorption: 7825*
- and rumen and intestinal bacteria: 7091
- Anticholinergics, effect on gastric acidity: 7754*

- Anticoagulants, contraindications, pancreatitis: 7987
- Antiemetics, ingestion of, treatment: 7538
- Anthelmintics, effect of duodenal juice on: 7510
- Antimetabolites, in treatment of ulcerative colitis: 7920*
- Antispasmodic agents, piperazine derivatives: 7229*
- Antiviral agents, correlation with virus particle size: 8207*
- Anus, cancer: 7849*, 7915
 - pretermatural, infants: 7863
 - sphincter, competence, measurement: 7848*
- Aortointestinal fistula: 7725
- Apparatus, bile pressure measurement: 8313
 - laparoscopy, peritoneum: 7328*
 - removal of parasites from blood vessels: 7363*
- Appendicitis, acute, due to cecal appendix volvulus: 7880
 - focal: 7896
 - pseudo-: 7895
- Appendix, carcinoid: 7870, 7881
 - carcinoma, metastatic: 7860
 - in femoral sac: 7885
 - Schultz-Dale detection of reagins: 7099
 - tumor: 7874, 7894
- Ascariasis, biliary tract: 8311
- Ascites, cirrhosis, treatment: 8258
- Atherosclerosis, surgery, ileocecal bypass: 7813*
- Bacteria, intestine, bile salt deconjugation capacity: 7083*
 - effect of experimental liver damage: 8151*
 - tropical sprue: 7820*
- Barium, diagnostic: 7326*
- β -Benzalbutyric acid, effect on bile secretion: 7199*
- Bezoar: 7639
 - small intestine: 7749
- Bile acids and salts, absorption: 7234*
 - gas chromatography, rev.: 7295
 - intestinal transport: 7141*
 - metabolism, in malabsorption: 7823*
 - rev.: 8094
- Bile duct, common, cancer, surgery: 7945*
 - catherization, cause of chronic pancreatitis: 7973*
 - cyst, perforated: 8307
 - effect of biliary dynamics: 8268*
 - exploration: 8306
- Bile duct, common, ligation, effect on hepatic regeneration: 7245*
 - perforation, spontaneous: 8315
 - pressure, psychological factors: 8310
 - cystic, non-calculous and non-malignant diseases, pathology: 8308, 8309
 - obstruction, radiomanometric technic: 8313
 - function, and α -naphthylisothiocyanate: 8269*
 - hepatic, strictures, surgical treatment: 8021*
 - intrapaneareatic, cancer, surgery: 8274*
 - obstruction: 8300
 - and secretin choleresis: 7194*
 - visualization: 8079
- Bile, estradiol metabolites: 7297
 - excretion, of decamethonium: 8304
 - flow, and α -naphthylisothiocyanate: 8269*
 - formation: 8139*
 - and lipid absorption: 7143*
 - liver, cholesterol conc., and gallstone formation: 8270*
 - pigments, protein binding, mechanism: 7249*
 - proteins: 7238*
 - secretion, β -benzalbutyric acid: 7199*
 - chlorpromazine: 8035*
 - liver explants: 7198*
 - and reflux perfusion: 7195*
- Biliary tract, ascariasis, children: 8311
 - atresia, surgery, child: 8273*
 - calculi, formation: 8275*
 - hemorrhage: 7393
 - cancer, with extrahepatic obstructive jaundice: 8031*
 - diseases, antispasmodic treatment: 7349
 - blood aldolase: 7392
 - diagnosis at reexploration: 8271*
 - headache: 8298
 - leukocyte alkaline phosphatase: 8120
 - dynamics, influence of common bile duct: 8268*
 - fistula: 7126*, 8295
 - function: 7180*
 - and anabolic agents, liver diseases: 8015*
 - motility, carp: 7231
 - reflux: 7109*
 - perfusion: 7195*
- Bilirubin, conjugated, liver uptake: 7242*

- Bilirubin conjugation, antiviral drug: 8188
- encephalopathy, experimental: 8011*
- formation: 7316
 - in normal, damaged, and Gunn rat livers: 8149*
- metabolism, liver, rev.: 7299
- protein binding, mechanism: 7249*
- Bismuth, colonic disease: 7856
- Blood, fecal, analysis: 7327*
- Blood flow, liver: 7244*
- Blood groups, and postcholecystectomy syndrome: 8267*
- Bones, involvement, nontropical sprue: 7814*
- Bulking agent, absorption: 7125*
- Cancer, abdomen, children, incidence: 7424
 - anus: 7915
 - appendix, metastatic: 7860
 - biliary tract, with extrahepatic obstructive jaundice: 8031*
 - cardia, and hiatus hernia: 7583
 - colon: 7833, 7877, 7912, 7913, 7914
 - villous: 7843*
 - duodenum: 7720
 - esophagus: 7551*
 - cytologic diagnosis: 7565
 - surgery: 7561, 7564
 - with tylosis: 7546*
 - gallbladder, primary, statistics: 8317
 - gastrointestinal, antigens: 7360*
 - diagnosis: 7462
 - ileum: 7714
 - intestine: 7747
 - liver, Africans: 8077
 - enzyme behavior: 8109
 - with extrahepatic obstructive jaundice: 8031*
 - serum transaminases: 8196*
 - thorotrast-induced, statistical study: 8184
 - thorotrast-retaining rate: 8185
 - pancreas: 7958
 - pancreaticoduodenal area: 7945*, 8274*
 - rectum: 7884
 - clinical study: 7866
 - diagnosis, P32: 7899
 - dissemination, blood stream: 7861
 - metastatic, diagnosis, lymphography: 7865, 7869
 - treatment: 7886
 - radiation: 7876
 - salivary gland: 7362*, 7380*
 - sigmoid, external resection: 7883
- Cancer, stomach: 7552*, 7611*, 7613*, 7619*, 7638, 7640, 7647, 7650, 7655, 7671, 7673, 7675
 - chemotherapy: 7665
 - chromatography of ascitic fluid: 7631
 - gastric juice: 7693
 - diagnosis: 7645
 - biopsy: 7646
 - etiology, ulcer surgery: 7796
 - exfoliative cytology: 7656
 - Quick-Pytel test: 7688
 - surgery: 7634
 - combined: 7690
 - comparative survival: 7633, 7669
 - and protein metabolism: 7652
 - and rectum, in succession: 7448
 - transplantable, and gastric erosion, rat: 7616*
- Carbohydrate, intolerance, familial, rev.: 7835
 - postgastrectomy: 7667
 - tropical sprue: 7826*
- Carbonic anhydrase, activity in stomach and intestine: 7079*
- Carcinogenesis, liver: 8163*, 8168*, 8176, 8178
 - and diet: 8155*
 - enzyme study: 8177
 - thyroid hormone and testosterone: 8161*
 - stomach and intestine: 7361*
- Carcinoid, appendix: 7881
 - with hematemesis: 7398
 - syndrome, gastrointestinal, argentaffin system: 7404
- Cardiovascular system, in cirrhosis: 8241*
 - portal visualization: 8039*
- Cations, protective effect against CCl₄-inhibition of enzyme: 8134*
- Cecostomy, carcinoma: 7927
- Cecum, carcinoid: 7905
 - ulcer caused by oxyphenbutazone: 7898
- Celiac disease: 7829
- Ceruloplasmin, serum, in liver disease: 8106
- Chemotherapy, effect on intestinal ammonia metabolism and bacterial count: 8151*
- Cholangiocystography, use of nivaline: 8072
- Cholangiography, codeine in: 8086
 - intraoperative, indications: 8112, 8297
 - retropancreatic findings: 8096
 - transhepatic, percutaneous: 8056
- Cholangitis, ascending, etiologic factors: 8027*

- Cholecystectomy, complications, incidence, relation to ABO blood groups: 8267*
 post-, syndrome: 8290
- Cholecystitis, acute, surgery: 7989, 8292
 and calcium carbonate-containing stones: 8266*
 diagnosis, children: 8289
 gallbladder motility after spa and mud therapy: 8286
 recurrence: 8299
 serum lipoproteins: 8293
 surgery, complications, incidence, relation to ABO blood groups: 8267*
- Cholecystography contrast medium: 8303
 retrograde, technic: 8272*
- Cholelithiasis: 8287, 8301
 induction, and thyroxine: 8276*
 pathogenesis, and cholesterol solubility in liver bile: 8270*
 serum transaminases: 8196*
- Cholera, symptoms, children vs. adults: 7374*
 vaccine, biological assay: 7504
- Cholera El Tor, epidemic: 7511
- Choleresis, secretin, and bile ducts: 7194*
- Choleretic: 8067
- Cholestasis, induction by drugs: 8015*, 8269*
- Cholesterol, atherosclerosis, prevention by ileal bypass: 7084*
 metabolism, effect of cholestyramine: 7322
 rat: 7323
 serum, changes in pregnancy: 7300
 determination of, ferric chloride method: 7350
- Cholestyramine, effect on cholesterol metabolism: 7322
- Chymotrypsin, active site polarity: 7215
 specificity, modifications: 7217
 kinetic behavior: 7218
- Circulation, and gastrin polypeptide: 7190*
- Cirrhosis: 8152*
 amino acid metabolism: 8238*
 ascites, diuretics: 8243*, 8244*, 8252, 8258
 biliary: 8255
 CCl₄-induced, and liver circulation: 8249*
 caused by infectious hepatitis: 8263
 and chromotosis: 8085
 coagulation factors: 8246*
 comparison of wedged suprahepatic venous pressure and free pressure: 8240*
- Cirrhosis, comparative studies: 8254
 and cystic fibrosis plasma lipids: 7375*
 diagnosis, Sandor's reticulo-endothelial bodies: 8236*
 epidemiology, Honduras: 8259
 etiology: 8248*
 fat-induced, liver histology: 8250*
 with β -globulin plasmacytosis: 8257
 hematochylia, significance: 8241*
 hematologic aspects: 8260
 and immunosedimentation of serum: 7376*
 infantile: 8262
 rev.: 8253
 liver sinusoids: 8140*
 pentose shunt, enzyme activity: 8261
 portasystemic shunt for, porta-systemic hemosiderosis: 8256
 postviral, immunological mechanism: 8193*
 renal function: 8014*, 8251*
 serum enzymes: 8196*, 8239*
 surgery, children: 8030*
 control of arteriovenous shunts: 8242*
 thioacetamide-induced, and liver regeneration: 8153*
 tolbutamide test: 8237*
 treatment with spironolactones: 8245*
- Coli endotoxin: 7274*
- Colitis, rev.: 7903
- Colo-esophagoplasty, indications in esophageal stricture: 7588
- Colon, absorption, fatty acids: 7138*
 blood supply, newborn African: 7113
 cancer: 7849*, 7877, 7897, 7913, 7914
 epidemiology: 7580*
 in ulcerative colitis: 7925*
 carbonic anhydrase activity: 7079*
 carcinoma: 7927

Preface

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, cause and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from virtually every medical journal published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

Acknowledgment

We wish to acknowledge gratefully the assistance of the National Library of Medicine in the preparation of this publication. The National Library of Medicine, through MEDLARS (Medical Literature Analysis and Retrieval System), is providing a recurring bibliography of gastroenterology-related citations which forms a part of the literature included in this publication as citations or abstracts.

Use of funds for printing this publication
approved by the Director of the Bureau of
the Budget on August 26, 1965

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, \$8.50; foreign \$10.75; and \$1.00 per single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by Index Medicus. For journals not covered by Index Medicus, the abbreviations (with some modifications) found in World Medical Periodicals, 3rd Edition, are used.

LANGUAGE ABBREVIATIONS

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotrophic hormone	mM	millimolar
admin.	administered, administration	μ M	micromolar
ADP	adenosine diphosphate	max.	maximum, maximal
ATP	adenosine triphosphate	mc, μ C	milli-, microcurie(s)
approx.	approximately	mg	milligram(s)
av.	average(d)	min.	minute(s)
$^{\circ}$ C	degrees centigrade	ml	milliliter(s)
cm	centimeter(s)	mm	millimeter(s)
CNS	central nervous system	mo.	month(s)
conc.	concentrate(d), concentration(s)	MTD	maximum tolerated dose
cpm	counts per minute	p.o.	orally
DNA	deoxyribonucleic acid	ppm	parts per million
e.g.	for example	r	Roentgen
g	gram(s)	RBC	red blood cells (erythrocytes)
μ g	microgram(s)	resp.	respectively
hr.	hour(s)	Rev.	review (only in cite)
i.m.	intramuscular	RNA	ribonucleic acid
inj.	injected, injection(s)	s.c.	subcutaneous
i.p.	intraperitoneal	soln.	solution(s)
I.U.	international unit(s)	U	unit(s)
i.v.	intravenous	UV	ultraviolet
kg	kilogram(s)	vol.	volume
LD ₅₀	median lethal dose(s)	WBC	white blood cells (leukocytes) or count
m	meter(s)	wk.	week(s)
M	molar	wt.	weight(s)
mEq	milliequivalent(s)	yr.	year(s)

PRE-CLINICAL SCIENCES

GENERAL

- 9 THE EFFECT OF STIMULATION OF THE INTEROCEPTORS OF THE ILEOCECAL REGION ON CARDIAC FUNCTION, RESPIRATION AND CEREBRAL BIOELECTRIC ACTIVITY. (ECG). (Ger.) Lindemann, M. (Humboldt U., Berlin), W. Rüdiger and S. Meyer. Activ. Nerv. Sup. (Praha) 8(1):1-12, 1966.

Cats, mechanical interoceptive stimulation by inflation of rubber balloons con-
 ned in surgically-constructed repositories in the ileocecal region produced
 iable effects. In some animals, a slight increase in the frequency of the heart
 t was seen; in some, a slight decrease; in one case, an initial decrease
 lowed by increase to above the pre-stimulation frequency. In similar, but even
 s marked fashion, breathing became slower or faster; or, in some cases, the
 th of respiration was increased or diminished. The changes observed could not
 related to electroencephalographic changes, nor were the latter consistent.
 etition of interoceptive stimulation resulted in habituation within a short
 e. Such stimulation failed to produce an arousal reaction consistently, al-
 ough the animals responded invariably to exteroceptive stimulation.

- 20 PUROMYCIN INHIBITION OF CHANGES IN GLUCOSE-EVOKED POTENTIAL RECORDED IN
 GOLDFISH INTESTINE AFTER PERIODS OF TEMPERATURE ACCLIMATIZATION. (E.)
 Smith, M. W. (U. Cambridge, England). Experientia 22(2):252-253, 1966.
 e glucose-evoked potential of the intestine taken from goldfish which were acclima-
 zed to 8°C increased rapidly as the incubation temperature was raised from 7.5-13°C
 ase 1) and then more slowly as the incubation temperature was increased from 13-
 °C (Phase 2). If the goldfish were inj. i.p. with either 0.9% NaCl or puromycin
 hr. prior to measurement, this same pattern was maintained. However, if the en-
 vironmental temperature was changed from 8 to 25°C 21 hr. prior to measurement, the
 nge of Phase 1 extended to 23°C and the i.p. inj. of puromycin 1 hr. before the
 vironmental change inhibited this extension of Phase 1.

- 21 ELECTROENCEPHALOGRAPHIC CHANGES IN RABBITS FOLLOWING INDUCTION OF DUODENAL
 HYPEROSMOSIS AND FOLLOWING INFUSION OF SEROTONIN. (Ger.) Gati, T. (U.
 Budapest, Hungary), I. Farkas, I. Dési and K. Gyenge. Zschr. Gastroent.
 4(1):33-35, 1966.

essentially identical electroencephalographic changes were seen in waking rabbits
 rring i.v. infusion of serotonin creatinin sulfate and 2-3 hr. after duodenal in-
 illation of hypertonic glucose or saline soln., which also induces dumping syn-
 rome and characteristic circulatory disturbances. The changes consisted of an in-
 ease in frequency and decrease of amplitude resembling those seen in desynchroni-
 ation, and of repeated disturbances of normal resting rhythms by dysrhythmic wave
 rops of 1-2 seconds duration and 200-300 μ Volt intensity, appearing above the
 ensorimotor centers and followed by paroxysmal potentials. In a few instances,
 vere spiking was observed in the absence of previous appearance of these locali-
 ed, dysrhythmic wave groups. The authors conclude that intraduodenal instillation
 f hypertonic soln. may release free serotonin within the intestine, thus stimulat-
 ng abnormal cerebral cortical activity and exciting the Bezold-Jarisch reflex by
 ultaneous diminution of blood pressure and the pressor reflex of the carotid
 erty.

- 22 SERUM ALKALINE PHOSPHATASE IN PREGNANCY: AN IMMUNOLOGICAL STUDY. (E.)
 Birkett, D. J. (U. Sydney, Australia), J. Done, F. C. Neale and S. Posen.
Brit. Med. J. 1(5497):1210-1211, 1966.

ternal serum alkaline phosphatase resembles placental alkaline phosphatase in its
 eat stability, substrate specificity and other characteristics. Serum alkaline
 osphatase in the fetus shows none of these characteristics. A purified human
 acental alkaline phosphatase was inj. into rabbits. From the pooled rabbit sera
 anti-placental γ -globulin was prepared which was incubated with serum from

GENERAL

various subjects. The alkaline phosphatase in maternal sera at term was partially inactivated by the anti-human placental alkaline phosphatase antibody. No such inactivation was seen in sera from non-pregnant subjects or newborn infants. This provides strong evidence that serum alkaline phosphatase elevation in pregnancy is due to circulating placental enzyme. It is shown not to be intestinal in origin.

- 8323 DNA SYNTHESIS IN THE KIDNEY AND SMALL INTESTINE OF HYPOPHYSECTOMIZED RATS AFTER PARTIAL HEPATECTOMY. (Ger.) Rabes, H. (U. Munich, Germany). Naturwissenschaften 53(12):308, 1966.

In rats undergoing excision of 66% of the liver, 30 days after transsphenoidal hypophysectomy and 41 hr. before inj. of radioactive thymidine 1 hr. prior to sacrifice renal synthesis of DNA was 193% higher than in hypophysectomized but non-hepatectomized controls. At the same time, the uptake of radioactive thymidine into the small intestine was diminished by 15%. It is concluded that alteration of the pool of DNA precursors, following hepatectomy, acted as a nonspecific cause for an increase of specific activity in the kidney.

- 8324 STUDIES OF THE CULTIVABLE FLORA OF NORMAL HUMAN FECES. (E.) Van Houte, (Harvard Sch. Med., Boston, Mass.) and R. J. Gibbons. Antonie Leeuwenhoek 32(2):212-222, 1966.

Nearly 80% of the flora present in fecal samples from 8 healthy adults consisted of gram-negative or gram-variable obligatory anaerobic rods (plated on blood-agar plates) which were considered to be Bacteroides. In addition, it was found that coliforms, streptococci and lactobacilli were regularly present in conc. of 10^6 - 10^8 organisms/g (wet weight material), while Veillonella, Streptococcus salivarius, Bacteroides melaninogenicus and staphylococci were present in lower conc. Fusobacteria were found in 1 sample, while Neisseria and spirochetes were never detected. Anaerobes (354 strains were isolated) were 40 times more numerous than facultative bacteria. In total, the bacteria comprised approximately 30% of the fecal mass.

- 8325 RESPONSES OF THE STOMACH TO SINUSOIDAL AND STOCHASTIC WAVES OF VIBRATION. (Ger.) Dupuis, H. (Max Planck Inst., Bad Kreuznach, Germany) and W. Christ. Int. Zschr. Angew. Physiol. 22(2):149-166, 1966.

Resonant (vibration) responses of the stomach to both sinusoidal and stochastic waves of vibration affecting the entire body were studied by X-ray cinematography in subjects seated on a hard surface covered by a thin layer of foam rubber and attached to a vibration mechanism capable of duplicating any type of vibrational pattern. After a full meal, the stomach resonated in response to sinusoidal vibrational patterns, with spiking of the resonance curve when impulse frequencies were 4-5 cycles per second only. There were marked individual differences in the height of the spikes, attributed to differences in stomach shape and gastric and abdominal muscle tone, which constitutes a self-contained mechanism for damping such resonance by absorbing the vibrations. Studies of resonant responses to transverse vibration confirmed that the stomach has an inherent resonating frequency which lies within or slightly above the range of resonating frequencies exhibited by the body as a whole. Filling the stomach with liquids, instead of normal food, had no effect on the resonance. Impulse vibrations of the same intensity induced significantly stronger resonant responses when frequencies were 2.0-4.5 cycles per second, rather than above or below. Gastric secretion appeared to be increased during resonance, although passage time was not altered. Protective abdominal belts increased, the resonance induced by stochastic, vertical vibrational patterns which duplicated patterns recorded in the seat of a wheel-propelled, springless tractor traveling on a bad stretch of unpaved rural road. However, a shock-absorbing seat reduced the resonant response of the stomach by approx. 43%; the amount of vibration to which the lumbodorsal spine was subjected, by approx. 53%.

- 8326 THE WASH-OUT OF INTRAARTERIALY INJECTED KRYPTON⁸⁵ FROM THE INTESTINE OF THE CAT. (E.) Lundgren, O. (U. Goteborg, Sweden) and M. Kampp. Experimentia 22(4):268-270, 1966.

The tissue clearance technic of measuring the disappearance of intra-arterially injected krypton⁸⁵ (Kr⁸⁵) seems to be suitable for measuring blood flow distribution in the cat intestine. In order to evaluate this technic, a continuous record of

arterial blood pressure and venous outflow from the jejunum was made simultaneously. Prior to inj. Kr^{85} , atropine and isopropyl norepinephrine were admin. and the splanchnic nerves were cut. The Kr^{85} wash-out curve showed 4 monoexponential components whose localization and functional significance are currently being investigated and are speculated to be as follows: (I), a fast component, indicates a shunting mechanism of considerable magnitude, possibly due to counter-current exchange; (II) this, along with I, seems to derive from the mucosal and submucosal layers and indicate a blood flow 400-1400 (I) and 30-70 ml/min./100g (II); (III) indicates a blood flow of 2-21 ml/min./100g in the intestinal muscularis; and (IV), a very slow component, arises from a source outside of the intestinal wall.

- 27 EFFECT OF INTESTINAL FLORA ON THE DEVELOPMENT OF IMMUNE REACTIONS IN ONTOGENESIS. (Cz.) Lodinová, R., V. Jouja and A. Lanc. Cesk. Pediat. 21(4): 289-295, 1966.

The Escherichia coli content of the intestinal tract was determined in 8 breast-fed and 5 bottle-fed infants. No significant difference in the number of organisms was found. Antibodies against their own E. coli organisms in the mothers were present at a titer of 1:128. In the placental blood, 86% of the newborn had a titer of 1:16. The titer of their own antibodies increased with age, were demonstrable in isolated sera at 4 weeks of life, and in 46% of children between 3-4 mo. of age. The skin tests were positive only in 8-15% of children at the age of 1-2 mo. From 2.5-9 mo. of age, they were positive in 74-92% of children. The positive skin test agreed with the presence of endotoxin antibodies. Breast-fed and bottle-fed children come into contact in the first days of life with the O antigen of E. coli. They receive low titers of antibodies from the mother, and begin to form their own antibodies in the first months of life. Contact with the endotoxin induces sensitization which may be demonstrated by a skin test from the age of 2.5 mo. on. When alien, non-pathogenic E. coli were transferred to the intestinal tract of 4 children, the titer of this type of E. coli was significantly higher than the titer of antibodies against the naturally present E. coli.

- 28 RESPIRATORY ACTIVITY OF RAT INTESTINAL MITOCHONDRIA. (E.) Symons, L. E. A. (C.S.I.R.O., Glebe, New South Wales, Australia). Nature (London) 210(5034): 422-423, 1966.

Mitochondria isolated from rat small intestinal mucosa and placed in a medium of 0.25 M of sucrose and 0.003 M ethylenediamine tetraacetic acid can be protected from unsaturated fatty acids (liberated by homogenation) by the addition of 1.5% bovine serum albumin (I) to the medium. This isolation with I substantially increased and sustained the rate of QO_2 (N) for succinate and produced a high rate of activity for such substrates as glutamate, malate and α -oxoglutarate. Without I, these last three gave only endogenous rates. With I the mitochondria were small, non-vacuolated and the cristae were well defined; the opposite occurred without I.

- 329 INTESTINAL ALKALINE PHOSPHATASE IN HUMAN LYMPH AND SERUM. (E.) Keiding, N. R. (U. Aarhus, Denmark). Scand. J. Clin. Lab. Invest. 18(2):134-140, 1966.

Electrophoretic separation of human serum, lymph and small intestinal fluid showed that the phosphatase fractions of the lymph and intestine are similar and that they differ from those of the serum. Lymph and intestinal fluid phosphatase both showed a comparatively lower substrate affinity towards p-nitrophenylphosphate than did the serum phosphatases. In contrast, lymph and intestinal fluid samples markedly inhibited L-phenylalanine (using phenyl phosphate as the substrate); with serum samples the inhibition was mild. The likeness of these parameters indicated that the phosphatase fractions of lymph are identical with those in the intestinal fluid.

- 330 STUDIES OF THE ENZYMATIC APPARATUS OF EPITHELIAL GALLBLADDER CELLS IN SHEEP. (Fr.) Bernard, S. (U. Nantes Sch. Med., France), M. Le Cam, J. C. Dubin and Y. Madec. C. R. Soc. Biol. (Paris) 159(12):2387-2391, 1965.

Comparative measurements of enzymatic activity in homogenates of sheep liver and of epithelial tissue derived from sheep gallbladder confirmed the existence of intense

GENERAL

metabolic activity in the epithelial tissue in question. Glucose-6-phosphate dehydrogenase and glutathione reductase showed levels of activity equal to or somewhat superior to those seen in the liver. As compared to hepatic levels, pyruvate kinase was 3 times more active, and intense glycolytic activity was shown in the absence of consumption of oxygen or demonstrable aerobic biosynthesis of ATP. Lactic dehydrogenase was somewhat more active than it was in the liver; fructose-1,6-diphosphatase was approx. equally active; catalase showed only 20% the amount of activity; glucose-6-phosphatase was not demonstrable.

- 8331 COMBINED AUTORADIOGRAPHY AND FLUORESCENCE MICROSCOPY. LOCALIZATION OF LABELLED 5-HYDROXYTRYPTOPHAN IN RELATION TO ENDOGENOUS 5-HYDROXYTRYPTAMIN IN THE GASTROINTESTINAL TRACT. (E.) Hammarstrom, L. (Karolinska Inst. Stockholm, Sweden), M. Ritzen and S. Ullberg. *Experientia* 22(4):213-215, 1966.

Autoradiographic and fluorescence microscopic studies were conducted simultaneously on gastric and intestinal wall specimens from an adult female mouse admin. i.v. 3 mg/kg of 1 μ Ci H³-DL-5-hydroxytryptophan (1) 4 hr. previously. The duodenal cells were more intensely fluorescent than the gastric cells, while the gastric cells showed much stronger uptake of the labelled substance. The fluorescence seems to indicate the storage of endogenous amine and the uptake of radioactivity appears to reflect rate of synthesis of the amine; therefore, despite the larger cellular depot of 1 seen in the duodenal cells, there seems to be a greater production of 1 in the gastric cells. The formation of 1 seems to be more rapid in young cells located at the bottom of the crypts and then to decrease continuously during the cell migration towards the gastric lumen.

- 8332 STRESS AND DIETARY INFLUENCE ON THE DIRECT OXIDATIVE PATHWAY OF CARBOHYDRATE METABOLISM IN THE INTESTINE. (E.) Pfeiffer, C. J. (Ames Res. Ctr., NASA, Moffett Field, Cal.) and J. R. Debro. *Arch. Int. Physiol.* 74(1):97-105, 1966.

Changes in 6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase activity in rat jejunal mucosa were studied in 9 groups of rats (10-19/group) in stress and refeeding experiments. Stress by starvation (48 hr.), starvation (42 hr.) plus pylorus ligation (17 hr.) or restraint (18 hr.) or hydrocortisone (40 mg i.m.) all significantly depressed hexosemonophosphate shunt activity. The greatest depression was seen following starvation plus pylorus ligation. After 48 hr. starvation, glucose (3 g p.o.) or complete diet refeeding significantly increased hexosemonophosphate activity above control (fed animals) values. The most marked effect followed refeeding with the complete diet. Typical gastric ulcer patterns were seen in the pylorus-ligated and restrained groups. It was concluded that rat jejunal mucosa is highly responsive to environmentally induced stress and refeeding situations. Alteration of carbohydrate metabolism of intestinal mucosa appears to play some role in the production of mucosal lesions.

- 8333 LECITHINASE AND LYSOLECITHINASE ACTIVITY IN RAT TISSUE. (E.) Robertson, A. F. (Ohio State U. Coll. Med., Columbus). *Biochim. Biophys. Acta.* 116(2):379-381, 1966.

The activity of lysolecithinase was never less than that of lecithinase in the following rat tissue homogenates: small intestine, large intestine, stomach, kidney, liver, lung, heart, brain and spleen. These activities were not separable by an ammonium sulfate fractionation. When pools of α^1 -lysolecithin (α^1 -acyl-GPC) and α^1 -lysophosphatidylethanolamine (α^1 -acyl-GPE) were used in an attempt to saturate or inhibit the lysolecithinase, no lecithinase activity directed at the α^1 fatty acid could be demonstrated. It is possible that there are two lysolecithinases with positional specificity, one acting only on α^1 -acyl-GPC and one acting only on β -acyl-GPC and that if the pool had consisted of β -acyl-GPC rather than α^1 -acyl-GPC, α -lecithinase activity might have been demonstrated.

- 8334 KINETICS OF INTESTINAL EPITHELIAL PROLIFERATION: EFFECT OF VAGOTOMY. (E.) Silen, W. (U. California Sch. Med., San Francisco), O. Peloso and B. F. Jaffe. *Surgery* 60(1):127-135, 1966.

GENERAL

1 group of animals (6 dogs), biopsies of large and small intestinal mucosa and mucosa were obtained at laparotomy 90 min. after i.v. inj. of 1.3 mc tritiated thymidine. Total vagotomy and pyloroplasty were performed on 4 dogs; pyloroplasty alone on 2. Repeat laparotomy was performed 2 or 6 wk. later and biopsies of the same sites were made, again 90 min. after i.v. inj. of 1.3 mc tritiated thymidine. In a second group (7 dogs), Thiry-Vella fistulas were constructed, beginning 36-38 cm distal to the ligament of Treitz. After at least 2 mo. recovery, 3 mc tritiated thymidine were inj., i.v.; followed in $\frac{1}{2}$ -72 hr. by biopsy of the mucosa in one of the stomas of the fistula. The same procedures were repeated at least 6 wk. after vagotomy and pyloroplasty in 5 dogs, pyloroplasty alone in 1, sham laparotomy in 1. Microautoradiographic studies showed a significant decrease in the labeling index in all intestinal segments in all dogs 2 wk. after surgery, probably indicating prolongation of the progenitor cycle as a nonspecific surgical reaction. This effect had disappeared at 6 wk. in all animals, and vagotomized animals (only) showed significantly increased proliferation of epithelial cells in the duodenum and jejunum, accompanied by a significant reduction of total replacement time.

335 GRADED ENTERECTOMY IN Escherichia coli SHOCK. (E.) Evans, W. E. (Marquette U. Sch. Med., Milwaukee, Wis.), R. T. Shore and J. C. Darin. Arch. Surg. (Chicago) 93(1):196-199, 1966.

A total of 72 adult mongrel dogs were used to test the protective effect of enterectomy of different grades and regions, and also enterotomy and sham operation upon survival after i.v. inj. of E. coli endotoxin, 2 mg/kg. One wk. after surgery the animals and intact controls were inj. with toxin and observed for survival. In one series of graded distal enterectomies, 90% (10 dogs), 75% (7 dogs), 50% (11 dogs) and 25% (10 dogs), the 48-hr. survival showed no appreciable difference, ranging from 50-64%. Death occurred in all 5 controls. In another series 8 dogs had 50% proximal enterectomy, 8 had enterotomy, and 8 had sham operation. All of these and 5 controls were dead at 48 hr. All surviving animals were killed and autopsied at 48 hr. When the distal 90% of the small intestine was removed prior to inj. of the toxin, protection was afforded to slightly more than half the animals. This protection was not lost when the distal resection was reduced to 5%. Proximal intestinal resection did not result in survival. Shock of sham operation and enterotomy were also without effect on survival.

336 DIHYDROFOLATE REDUCTASE FROM GUINEA PIG LIVER AND SMALL INTESTINE. (E.) Bertino, J. R. (Yale U. Sch. Med., New Haven, Conn.), A. T. Iannotti, J. P. Perkins and D. G. Johns. Biochem. Pharmacol. 15(5):563-571, 1966.

337 ANTIGENICITY OF SALIVA PAROTIN A. (Jap.) Shinoda, M., Y. Takaqi and B. Tamaoki. Yakugaku Zasshi (J. Pharm. Soc. Jap.) 86(4):306, 1966.

338 PURIFICATION AND PROPERTIES OF WHALE PANCREATIC RIBONUCLEASES. (E.) Irie, M. (U. Tokyo), T. Yamada and Y. Ukita. J. Biochem. (Tokyo) 59(4):344-352, 1966.

339 ANTIGENIC STUDIES ON SABIN TYPES 1 & 3 POLIOVACCINE VIRUS DURING 1 TO 7 PASSAGES IN THE HUMAN INTESTINAL TRACT. (E.) Furesz, J. (Dept. Nat. Health Welfare, Ottawa, Canada), R. E. Armstrong, P. Moreau, W. Yarosh and F. P. Nagler. Am. J. Epidemiol. 83(3):501-508, 1966.

3340 IN VIVO DEMONSTRATION OF LACTIC ACID PRODUCTION IN THE DIGESTIVE TRACT OF GERMFREE RATS BY LACTOBACILLUS FLORA ALONE. (Fr.) Ducluzeau, R. (Anim. Prod. Res. Lab., Jouy-en-Josas, Yvelines, France), P. Raibaud, E. Sacquet and G. Mocquot. C. R. Acad. Sci. (Paris) 262(2)(Series D):321-324, 1966.

3341 NUCLEOLAR PROTEINS OF RAT LIVER AND WALKER TUMOUR. (E.) Grogan, D. E. (Baylor U. Coll. Med., Houston, Tex.), R. Desjardins and H. Busch. Cancer Res. 26(5):775-779, 1966.

CELLULAR STRUCTURE AND MORPHOLOGY

- 8342 THE IMPORTANCE OF THE INTERNAL SPHINCTER FOR ANAL CONTINENCE. (Ger.) Stelzner, F. (U. Hamburg, Germany), K. Fleischhauer and A. F. Holstein. Langenbeck. Arch. Klin. Chir. 314(2):132-136, 1966.

A study of 33 sections of the terminal end of the intestinal tract confirmed that the internal (white) anal sphincter is totally devoid of intramural ganglionic cells between the linea ano-cutanea and the linea ano-rectalis, and that such cells begin to be demonstrable only with the beginning of the rectal ampulla. The authors conclude that this absence of ganglionic cells explains the phenomenon of habitual anal continence since it indicates a spontaneous, permanent contraction of the internal sphincter. This, in turn, can be reinforced by voluntary contraction of the external sphincter, but only for a short time (i.e., until a stronger peristaltic wave ensues). Such an absence of ganglionic cells, extending from the internal anal sphincter to the beginning of the sigmoid, would provide a satisfactory explanation of the involuntary "hypercontinence" seen in patients with megacolon. The authors also suggest that any attempt to create continence by substituting voluntary muscle tissue for both the internal and external sphincters can be only partially successful.

- 8343 BIOLOGY OF ENDOCRINE CELLS (FEYRTER'S CLEAR-CELL-ORGAN) IN THE DIGESTIVE TRACT. (IN THE LIGHT OF STUDIES OF RABBIT STOMACH.) (Ger.) Ratzenhofer, M. (U. Graz, Austria). Klin. Wschr. 44(3):109-115, 1966.

An electronmicroscopic study of so-called clear cells in the gastric mucosa of the rabbit confirmed that a single kind of cell was involved, despite the existence of different kinds of granula-formation. Short-lasting, transitional phases were also observed, with one kind of granulation being replaced by another. Black granula were classified as osmiophile, grey granula as osmiophobe, depending on the degree of their affinity for osmic acid, which, in turn, appeared to vary directly in proportion to their content of a reducing agent, 5-hydroxytryptamine (I). Argentaffin, chromaffin, and similar cellular characteristics were also related directly to the cell's I-content. This was taken to indicate a secretion cycle in which the chromoargentaffin cell represents the fully differentiated cell, rich in I; the argyrophile cell, the state which follows discharge of the hormone from the granula; and the "empty" cell (the cell without granula), a subsequent exhaustion state, at the end of which, new granula-formation may be seen. Clear cells, as such, appeared only after combined formaldehyde-osmium fixation and appeared to be largely an effect of the formaldehyde itself. They ranged from "empty" to rich in granula, with partial autolysis of the cytoplasm (which contained a great deal of water), atrophy of the organelles and formation of many, large vacuoles. The author concludes that such cells should be known simply as E-cells (endocrine cells), with additional description, when desired, as argentaffin E-cells, argyrophile E-cells, etc.

- 8344 THE DISTRIBUTION OF LIVER SEGMENTS. (Ger.) Platzer, W. (U. Vienna, Austria) and H. Maurer. Acta Anat. (Basel) 63(1):8-31, 1966.

A detailed anatomic study of 33 liver specimens inj. with Latex of various colors through the right and left main branches of the portal vein showed such a variety of individual differences in the segment outlines in both the right and left lobes that the authors were unable to represent them by a general model. Further studies of the entire portal system and its supply areas are bound to result in discovery of other segments and additional variations of segment borders. It is believed that in vivo methods of visualizing the vascular systems do not give a true indication of the area they supply and may, therefore, not be used to demonstrate segments on the liver surface.

- 8345 THE ADRENERGIC NERVES OF RAT SALIVARY GLANDS AFTER EXCRETORY DUCT LIGATION. (E.) Andén, N. E. (U. Goteborg, Sweden), K. A. Norberg and L. Olson. Acta Physiol. Scand. 66(4):501-506, 1966.

A conspicuous reduction of acinar cell cytoplasm occurred in atrophied submaxillary and sublingual glands of rats (caused by ligation of the main excretory duct); this was not accompanied by a corresponding disappearance of the adrenergic nerve

CELLULAR STRUCTURE AND MORPHOLOGY

its transmitter, norepinephrine. Although the total norepinephrine content of the glands had decreased slightly, the value in terms of $\mu\text{g/g}$ was 2-3 times greater than the atrophied gland which was about 1/3 the size of the gland on the opposite side where no ligation was performed. In addition, there was an increased number of mast cells containing 5-hydroxytryptamine in the atrophied glands. This increase was probably due to an inflammatory response. These results would indicate that a salivary gland with atrophied acinar cells which gives rise to an increased density of the adrenergic ground plexus could be valuable in studies on postsynaptic events in adrenergic transmission.

- 46 EFFECTS OF MOLAR CONCENTRATION OF FIXATIVE UPON THE FINE STRUCTURE OF OXYNTIC CELLS. (E.) Vial, J. D. (Catholic U., Santiago, Chile) and H. Orrego. Protoplasma 61(1-2):164-180, 1966.

A step-by-step alteration in the ultrastructure of oxyntic cells from the toad Bufo marinus was produced by changing the conc. of the fixative with sucrose from 0.13 M to 0.22 M and then to 0.39 M. A quite different and reproducible image was seen at each different tonicity. With the low conc, the cells swell, often filling the lumen of the gland, the cytoplasm is clear, the apical pole membrane is folded into thick, club-like villi and the supranuclear region shows many rounded vesicles. With the high conc., the height of the cell is reduced so that the lumen is wider, only a few thin microvilli are present, the cytoplasm seems fibrillar and a system of thin tubules is found in the supranuclear region. These tubules disappear upon stimulation with histamine and the area of the cell membrane increases concomitantly, indicating mutually inter-convertible membranous structures. In vivo treatment with water gives results similar to those seen with the low conc. The cisternae of granular endoplasmic reticulum, Golgi zone and mitochondria remained unchanged in different fixatives. Oxyntic cells of bats were also affected by the toxicity of the fixative, whereas other cell types remained unchanged.

- 47 GENESIS OF LIVER MITOCHONDRIA IN THE NEONATAL RAT. (E.) Ontko, J. A. (U. Tennessee Med. Units, Memphis). Life Sci. 5(9):817-825, 1966.
- In neonatal rats, the number of mitochondria isolated per g of fresh liver was approximately one-third the number seen in adult animals and increased progressively, postnatally, until adult values were reached on day 5 of life. Total nitrogen content per g of fresh liver was also approx. one-third the total content found in adults. This value increased progressively until adult values were reached on day 12 of life. The packed mitochondrial vol. tended to correlate, in general, with the number of mitochondria and total nitrogen content, suggesting that there were no large variations in the av. size and density of the harvested mitochondria derived at most postnatal age levels. The method employed for counting mitochondria is described in some detail and was felt to be a significant improvement over oil-immersion, phase-contrast microscopy.

- 348 FINE STRUCTURAL CHANGES AND LOCALIZATION OF PHOSPHATASES IN THE EPITHELIUM OF THE DUODENAL CRYPT OF X-IRRADIATED MICE. (E.) Hugon, J. (Nucl. Energy Stud. Ctr., Mol, Belgium) and M. Borgers. Histochemie 6(3):209-225, 1966.
- The ultrastructural localization of acid phosphatase was studied in the stem cells of the duodenal crypt of fasting adult male mice treated by whole-body irradiation (total 1350 r) and sacrificed 30 min. to 96 hr. later. Early ultrastructural changes included mitochondrial enlargement and membrane rupture, multiplication of dense bodies, formation of numerous cytolysosomes, and nuclear anomalies; by day 4-5, cell destruction was complete and the cell cytoplasm was reduced to a thin layer between the lumen of the crypt (where only atrophied microvilli remain) and the underlying edematous vascular tissue. Within 24 hr. after irradiation, initial elaboration of numerous vesicles containing lead phosphate in the Golgi area was followed by their gradual dispersion; the amount of cytochemically detectable acid phosphatase decreased progressively until it was practically absent by day 5. With the light microscope, acid phosphatase was frequently noted at sites similar to those of the alkaline phosphatases. Good correlation was observed between ultrastructural and cytochemical observations. The significance of the various changes is discussed.

CELLULAR STRUCTURE AND MORPHOLOGY

- 8349 CELL DYNAMICS IN THE INTESTINE OF THE MOUSE FROM LATE FETAL LIFE TO MATURITY. (E.) O'Connor, T. M. (Washington U., St. Louis, Mo.). Am. J. Anat. 118(2):525-536, 1966.

The villus-crypt epithelial cell population in the duodenum of white Swiss mice has two periods when the mitotic index is reduced 25%; one period is at birth and the other is from day 13-19 after birth. The mitotic index remains unchanged from postnatal day 21-48. By postnatal day 21, the villus-crypt height is 83% of the level reached by day 48. At birth, approx. 43% of the 48-day height is observed. No extrusion zones were observed in mice before birth, whereas a 3-fold increase in the rate of extrusion was observed between postnatal day 15 and 21. A rapid increase in absolute and relative intestinal weight was observed during postnatal days 15-23, but this was not accompanied by a rapid increase in length nor a disproportionate growth in villi-crypt height. Growth of the villus-crypt epithelial cell population appears to result from a rate of cell extrusion which is much lower than in the adult animal rather than from increased mitotic rates.

- 8350 CYTOLOGICAL CHANGES IN HEPATIC AND RETICULOENDOTHELIAL CELLS IN RABBIT LIVER FOLLOWING GONADECTOMY. (E.) Nathaniel, D. R. (Cedars of Lebanon Hosp., Los Angeles, Cal.) and E. J. H. Nathaniel. Am. J. Anat. 118(2): 537-549, 1966.

In adult male rabbits, deprivation of testicular hormones for 2 wk. following castration resulted in considerable increase of agranular, hepatic endoplasmic reticulum, which was conc. along the cell borders as well as intracellularly and which was demonstrably associated with the presence of glycogen bodies. Accumulation of glycogen was progressive, beginning with wk. 2, and was accompanied by progressive diminution of agranular reticulum from wk. 2 to wk. 4-6., at which time, however, smooth reticulum was still demonstrable along the sinusoidal borders. Considerable numbers of lipid vacuoles were also in evidence, surrounded by large masses of glycogen and smooth vesicles which had been formed from the agranular reticulum and which were now traversing the cytoplasm. The nucleus showed a moderate degree of chromatin condensation along the nuclear margin, accompanied by an increase of granular endoplasmic reticulum in the cell, suggesting a probable increase of the production of ribonucleic acid. In reticuloendothelial cells, the cell process was retracted, resulting in reduced surface area. The nucleus was considerably more compact and the cell as a whole appeared quiescent. It is concluded that previous reports of reduced phagocytic activity of the Kupffer cells in castrated rabbits may be related to such decrease of the cells' surface area or to changes in the property of the cell membrane.

- 8351 INTESTINAL VILLI IN RHESUS MONKEYS. (E.) Sehgal, A. K. (Inst. Postgrad Med. Ed. Res., Chandigarh, India), R. N. Chakravarti, N. R. Mysorekar and P. N. Chhutanni. Nature (London) 210(5039):972-973, 1966.

Villi configuration was studied by dissection microscopy in duodenal, jejunal, and ileal specimens obtained from 22 rhesus monkeys (av. wt. 2.8 kg) fed a mixed diet of bananas, soaked gram, and wheat bread for 1-5 days before sacrifice. Distribution of villus types was as follows: leaf (or tongue)-like in 56 specimens (65%); finger-like in 6 (7%); mixed in 10 (12%); extra-broad curved in 14 (16%). More than 50% of the duodenal specimens showed broad-curved villi; finger-like types were not found in the duodenum. The jejunum and terminal ileum showed similar patterns with a predominance of leaf-like villi. Many intermediate stages between the 3 types were observed. The ratio of villus height to crypt varied between 6:1 and 3:1 depending on the type of villi; values were higher for finger-like villi and lower for leaf-like or extra-broad curved villi.

- 8352 THE NUCLEAR PATTERN OF THE PARENCHYMAL CELLS OF THE LIVER AFTER PARTIAL HEPATECTOMY. (E.) James, J. (U. Amsterdam, The Netherlands), M. Schopman and P. Delfgaauw. Exp. Cell Res. 42(2):375-379, 1966.

Following partial hepatectomy where 65% of the liver weight is removed by resection of the median and left lateral lobe, the nuclear pattern of the parenchymal cells

CELLULAR STRUCTURE AND MORPHOLOGY

After the drop in mitotic and endomitotic activity at the beginning of the third postoperative day still differed greatly from normal. A drop in the percentage of mononuclear diploid cells, and particularly of binuclear diploid cells (less than 10% of normal) occurred. The relative proportion of binuclear tetraploid cells showed a significant, but less obvious, decrease. In the strongly increasing mononuclear polyploid cells, the changes were relatively greatest in the mononuclear octoploid cells which increased almost 10-fold. Shortly after operation, the tetra- and mononuclear tetraploid cells made up 90% of the population. By postoperative day 56, the population began to show a pattern shift back towards normalcy.

- 53 THE INNERVATION OF SALIVARY GLANDS. I. CHOLINESTERASE-POSITIVE NERVES IN NORMAL GLANDS OF THE CAT. (E.) Garrett, J. R. (King's Coll. Hosp., London, S. E. 5). J. Roy. Micr. Soc. 85(2):135-148, 1966.

The peripheral innervation of cholinesterase-positive nerves in the submandibular gland of the cat was very extensive with networks of fine nerves around acini which attained a complexity beyond exact analysis. In contrast, the cat parotid gland contained fewer nerves with a different distribution and no periacinar networks were seen. When the thiochrome cholinesterase histochemical technique and the diazoacetic acid method (electron microscope) were compared, it was found that each sensitive nerve 'fiber' seen by light microscopy actually represents the aggregation of a unit axon group plus the associated Schwann cell or end-on Schwann cell chain rather than an individual axon.

- 54 THE INNERVATION OF SALIVARY GLANDS. II. THE ULTRASTRUCTURE OF NERVES IN NORMAL GLANDS OF THE CAT. (E.) Garrett, J. R. (King's Coll. Hosp., London, S. E. 5). J. Roy. Micr. Soc. 85(2):149-162, 1966.

Electron microscopy of material taken from cat submandibular and parotid glands and fixed by osmium tetroxide revealed the presence of synapses only in association with parasympathetic ganglion cells in the submandibular gland. The total innervation of the parotid was less extensive than that of the submandibular gland. Peripheral non-myelinated axons, usually more than one, were found in association with Schwann cells and where the axon was partly bared of its Schwann cell investment the neuro-effector site was located. This arrangement was found in association with acinar cells, myoepithelial cells, intercalary duct cells, striated duct cells and blood vessels. Convergence of more than one axon on a single effector cell was not uncommon.

- 55 ULTRASTRUCTURAL ASPECTS OF DUODENAL CRYPTS IN X-IRRADIATED MICE AFTER CHEMICAL PROTECTION. (E.) Hugon, J. (Nucl. Energy Stud. Ctr., Mol., Belgium), J. R. Maisin and M. Borgers. Nature (London) 210(5037): 749-750, 1966.

The ultrastructure of duodenal crypt stem cells from BALB/c⁺ adult male mice was modified as follows after irradiation (1,350 r): mitochondrial dilatation within 10 min., increased number of lysosomes after 60 min. and the appearance of large autolysosomes after 180 min. The appearance of these lesions was delayed by i.p. inj. of aminoethylisothiourea (I) prior to irradiation. However, no important mitochondrial dilatation was observed 180 min. after irradiation when the mice were inj. with a mixture containing I plus glutathione and serotonin. Instead of the previously mentioned ultrastructural changes, needle-shaped structures were found in the vacuoles which seem to protect the cells from the early effects of irradiation.

- 56 CELLULAR AND SUBCELLULAR CHANGES IN INTESTINAL AND RENAL TUBULE EPITHELIAL CELLS INDUCED BY SODIUM SALICYLATE. (E.) Millington, P. F. (U. Bristol, England) and P. W. A. Tovell. Arzneimittelforschung 16(3): 354-359, 1966.

Consistent (morphologic) changes in the duodenal epithelium of rats were seen within 20-24 hr. after a single large dose of sodium salicylate (1.0 or 1.5 g/kg; by gastric intubation). When examined by the electron microscope, the intestinal epithelium contained areas with fewer organelles (mitochondria, nucleus and endoplasmic reticulum) in the basal region of the cells. These expanded regions were confined to the basal region and additional space was not usually found between

CELLULAR STRUCTURE AND MORPHOLOGY

the cell and the basement membrane as had been indicated in light micrographs. This effect seen in light micrographs was considered to be an artifact. Similar morphologic changes occurred in the kidney. No difference in response to this drug was seen between the sexes. Alteration in cell wall permeability is discussed as an explanation for these degenerative changes provoked by sodium salicylate.

- 8357 STRUCTURAL CHARACTERISTICS OF ARTERIES OF PANCREAS. (Rus.) Aganezov, S. A. (Pavlov Ist. Inst. Med., Leningrad). *Arkh. Anat.* 50(2):71-76, 1966.

Pancreatic artery structure was studied by various methods (injection, roentgenography, preparation, and corrosion) in 110 specimens obtained at autopsy from cadavers of various ages. Two principal structural types were observed: (1) branches of the superior pancreaticoduodenal artery were distributed in the head and isthmus of the gland, while branches of the main pancreatic artery were distributed throughout the body and tail of the gland; (2) branches of the inferior pancreaticoduodenal artery were distributed in the head of the gland, while the fine rami of the splenic artery were distributed throughout the isthmus, body, and tail. Anastomosis between arteries of the head and body of the gland were distributed either in the isthmus or right portion of the gland regardless of the structural type, which should be borne in mind during resection of the pancreatic head. The importance of knowledge of vascular structure in pancreatic surgery is discussed.

- 8358 ULTRASTRUCTURAL PHARMACOPATHOLOGY. I. COMPARATIVE MORPHOLOGY OF THE LIVERS OF THE NORMAL STREET DOG AND PUREBRED BEAGLE. A BASE-LINE STUDY. (E.) Stein, R. J. (Abbott Lab., Chicago, Ill.), W. R. Richter and G. Brynjolfsson. *Exp. Molec. Path.* 5(3):195-224, 1966.

The liver ultrastructure of 32 clinically normal beagle-type street dogs was found to differ from that of 14 clinically-normal registered beagles. The ultrastructure of the latter was found to be similar to the classic picture of liver structure as established for the laboratory rat; whereas with the street dogs, the following ultrastructural abnormalities were seen in at least 5 dogs: nuclear crystals, mitochondrial crystalloids, disorganized smooth endoplasmic reticulum, myelin figures and excess lipid. A total of 23 of these dogs showed abnormalities which seems to eliminate this source of dogs as an adequate animal for ultrastructural chronic toxicity work.

- 8359 STUDY OF THE ENDOTHELIUM IN CAPILLARIES OF THE VILLI OF SMALL INTESTINES IN MAN AND GUINEA PIG. (Ger.) Horstmann, E. (U. Hamburg, Germany). *Zschr. Zellforsch.* 72(3):364-369, 1966.

Histologic study of upper ileum of guinea pigs, and of a specimen obtained following gastroenterostomy on a 71-yr.-old patient showed that the endothelial lining of the capillaries facing the epithelium of the intestinal villi is very thin and contains numerous pores; the lining facing the opposite side has no pores, is much thicker, and also contains the cell nuclei.

- 8360 EFFECT OF CONTINUOUS IRRADIATION ON THE CELL CYCLE OF THE DUODENAL CRYPTS OF THE MOUSE. (E.) Leshner, S. W. and G. A. Sacher. *Argonne Nat. Lab. Ann. Rep.* (ANL-7136) 1965:46-47.

BCF₁ mice (100 days old) subjected to a daily exposure of 12 r for 570 days had a duodenal crypt cell cycle which was $4\frac{1}{2}$ hr. shorter than that in the nonirradiated controls. The cycles were measured by injecting the exposed animals for $\frac{1}{2}$ -20 hr. before sacrifice with 10 μ c of tritiated thymidine and then plotting the percent-labeled mitotic figure curves. This compensatory acceleration of the cell cycle by the duodenal crypt cells of the mice which have been exposed to continuous irradiation is brought about by a reduction in the S and G₁ phase (principally the G₁), as the G₂+M phase is the same as that of the control mice.

- 8361 DAMAGE AND RECOVERY IN DUODENAL CRYPT CELLS OF IRRADIATED MICE. (E.) Leshner, S. W. *Argonne Nat. Lab. Ann. Rep.* (ANL-7136) 1965:48-52.

Studies of duodenal crypt cells from a series of mice which were inj. with 10 μ c of

CELLULAR STRUCTURE AND MORPHOLOGY

initiated thymidine (1) immediately before a single 300-r exposure to Co^{60} gamma rays showed that crypt cells in the S phase are certainly heavily damaged, as there are aberrant mitotic figures and a number of karyolytic bodies. Since over 60% of the first mitotic figures are labeled, it appears that cells in S at irradiation are blocked in G_2 during the mitotic lag period rather than at the end of S. When counts of labeled nuclei were made on crypt squashes following inj. of 1 at close postirradiation intervals, the number of labeled nuclei/crypt began to drop immediately, indicating a slowing down of cells moving from G_1 into S. All phases of the cell cycle were affected by irradiation; the S phase was reduced more than an . in the 6-24-hr. postirradiation series. Recovery is not as rapid in cells in vivo as that postulated by others for cells in vitro.

- 362 KINETICS OF CELL PROLIFERATION IN THE INTESTINAL EPITHELIUM IN NONIRRADIATED MICE. (E.) Leshner, S. W., A. R. Salles and M. A. Jones. Argonne Nat. Lab. Ann. Rep. (ANL-7136) 1965:52-55.

Issue samples of duodenum taken from a series of 55-1050-day-old BCF₁ mice inj. with 5 μ c of tritiated thymidine showed that the crypt cell cycle increases with age and this increase is due primarily to changes in the duration of the S and G_1 phases. The following phase estimations were made on 100-day-old mice: cell cycle 13.25 hr., $G_2 + M = 1.8$ hr., S = 6.75 hr. and $G_1 = 4.7$ hr. The proliferative population is an "all-out" one and does not contain a reserve of G_0 cells. If production is increased, the cell cycle must be shortened.

- 363 CELL PROLIFERATION IN THE GALLBLADDER EPITHELIUM OF THE MOUSE. (E.) Fry, R. J. M., C. Weber and E. F. Staffeldt. Argonne Nat. Lab. Ann. Rep. (ANL-7136) 1965:55-57.

When BCF₁ mice admin. tritiated thymidine are placed on a diet containing 2% sodium taurochenodeoxycholate a marked increase in cell proliferation is seen in the gallbladder epithelium. By spacing the periods of admin. of the diet it is possible to produce a number of bursts of cell proliferation and to study the effects of repeated stimulation. In addition, chromosome preparations can be obtained. Thus, this system provides a good model for studying the following: ploidy, chromosome aberrations and proliferative capacity in relation to age and irradiation; the influence of repeated periodic proliferation on tumor incidence; and the relationship of proliferative activity to the induction of tumors by radiation. However, the variation in the response, particularly in relation to time, is a troublesome feature.

- 364 INORGANIC ALKALINE PYROPHOSPHATASE IN THE MUCOUS GLANDS OF THE DIGESTIVE ORGANS OF THE WHITE RAT. (Ger.) Fischer, E. (Inst. Pedagogy, Tech. Sch., Pecs, Hungary). Acta Histochem. (Jena) 23(5-8):332-333, 1966.

Using a modification of the original Korhonen method for alkaline pyrophosphatase (1) staining (pre-fixation with formalin-trichloroacetic acid), the author examined stomach, small and large intestine, salivary glands (submandibular and sublingual), liver and pancreas of white rats. The control sections were incubated either without substrate, or the enzyme was destroyed by 24-hr. fixation at room temperature in 10% formalin. Secretory cells in the mucous epithelium of small and large intestines showed intense 1 activity; the apical epithelium of the stomach somewhat less, the rest of the stomach lining none. Intensive activity was found in the sublingual glands while the mostly serous submandibular glands were negative, or barely positive. The exocrine and endocrine glands of the pancreas showed only a very weak, uncharacteristic shading; liver cells were somewhat better stained. It is concluded that, in addition to smooth muscles and RBC, intense 1 activity in the digestive tract is localized in the cells of the mucous glands.

ABSORPTION

- 75 IRON ABSORPTION AFTER PARTIAL GASTRECTOMY. A COMPARATIVE STUDY ON THE ABSORPTION FROM FERROUS SULPHATE AND HEMOGLOBIN. (E.) Hallberg, L. (U. Goteborg, Sweden), L. Söivel and B. Zederfeldt. Acta Med. Scand. 179(Suppl. 445):269-275, 1966.

Iron absorption from ferrous sulfate and hemoglobin was compared using a double radioiron method in 11 non-gastrectomized (4 normal and 7 iron-deficient subjects) and 13 gastrectomized (7 Billroth I and 6 Billroth II) patients. In normal non-gastrectomized subjects, the absorption of iron was the same from both ferrous sulphate and hemoglobin. In the iron deficient group, absorption from ferrous sulfate was approx. 3 times that from hemoglobin. In the Billroth I group, absorption of iron from both compounds was the same for normal non-anemic subjects when hemoglobin exceeded 14 g%. When the hemoglobin was less, iron absorption from ferrous sulfate and hemoglobin was increased, but was still less than that in non-anemic iron-deficient blood donors, indicating that a minor defect in absorption existed. In the Billroth II group, the 3 subjects with the lowest hemoglobin had a lower absorption from both ferrous sulfate and hemoglobin than the others, the reduction being most marked for ferrous sulfate. Billroth II patients experience a greater impairment of iron absorption than do Billroth V subjects.

- 376 ELECTRON MICROSCOPIC STUDY OF THE ROLE OF LIPID MICELLES IN INTESTINAL FAT ABSORPTION. (E.) Ashworth, C. T. (U. Texas Southwest. Sch. Med., Dallas) and J. F. Lawrence. J. Lipid Res. 7(4):465-472, 1966.

The intestinal intraluminal contents obtained from rats during the absorption of unsaturated fat contained osmophilic particles of 40-200 A which were similar to those seen during in vitro electron microscope studies of micellar soln. of oleic acid, monoolein and sodium taurocholate. Numerous similar particles were found between the microvilli and engaged in the fine filamentous coating of microvilli. In the lumen only, large emulsion-type droplets were also seen. The small particles were demonstrable in osmium-fixed material, with or without lead stains. Spherules of 1000 A with walls of 100 A were observed in the terminal web during fat absorption when they were more numerous and larger. It is proposed that during fat absorption micellar particles are engaged in the filamentous material covering the microvilli and then enter the absorptive cell either by molecular diffusion or by being incorporated into the walls of thick-coated spherules which then pass into the subapical cytoplasm.

- 377 OBSERVATIONS ON THE ACTIVE TRANSPORT OF BILE SALTS BY RAT AND HAMSTER ILEUM IN VITRO. (E.) Faust, R. G. (U. North Carolina Sch. Med., Chapel Hill) and S.-M. L. Wu. Biochim. Biophys. Acta 120(2):299-301, 1966.

The active transport of bile salts by everted sacs of rat and hamster ileum is reduced at bile salt conc. which are known to decrease the ATP level within the mucosal tissue. The initial placement of 6 and 24 mM sodium taurocholate or 3, 6 and 24 mM sodium glycocholate in the mucosal and serosal compartments of the rat ileum inhibited their active transport. With the hamster ileum, inhibition occurred with 6 or 24 mM of either bile acid. The effect of a steady removal of these bile salts by the portal blood circulation in vivo would probably permit higher conc. of bile salts before inhibition would occur.

- 8378 STUDIES ON INTESTINAL ABSORPTION OF VITAMIN C. I. ACTIVE TRANSPORT OF ASCORBIC ACID IN THE GUINEA PIG INTESTINE. (Jap.) Kubo, H. (Tokushima U. Sch. Med., Japan). Shikoku Igaku Zasshi (Shikoku Acta Med.) 22(1): 34-40, 1966.

In experiments using guinea pig small intestine, results confirmed the fact that ascorbic acid is actually absorbed following in vivo admin. In order to elucidate the mechanism of absorption, in vitro studies were performed using the Wilson intestinal loop method (without eversion). The following results were observed:

absorption was not proportional to the amount admin.; absorption occurred against the conc. gradient in the small intestine; aeration accelerated absorption; no marked differences in absorption were observed in the various parts of the intestine, except the duodenum; absorption was almost constant in a pH range of 6.5-7.7; 2,4-dinitrophenol partially inhibited absorption. It is concluded that an active as well as passive, transport mechanism is present in the absorption of ascorbic acid by the small intestine.

- 8379 AMINO ACID TRANSPORT BY THE SMALL INTESTINE OF THE RAT. ON THE COUNTERFLOW PHENOMENON AS A CAUSE OF THE ACCELERATING EFFECT OF LEUCINE ON THE TRANSINTESTINAL TRANSPORT OF DIAMINO ACIDS. (E.) Munck, B. G. (U. Copenhagen, Denmark). *Biochim. Biophys. Acta* 120(2):282-291, 1966.

Using sacs of everted small intestine from male albino rats which were fasted for 24 hr., the rate found for transintestinal transport of lysine, and the acceleration of this by leucine, was one that would indicate the existence of separate carriers of neutral and basic amino acids. In the presence of both lysine and leucine, the transport mechanism of the latter created and maintained (on the serosal side) a conc. of leucine sufficient to exert a counterflow effect on the transport of lysine. This acceleration by leucine also occurred in the presence of arginine and ornithine. However, these basic acids did not accelerate the transport of leucine in a similar manner which would again indicate the presence of 2 transport systems with distinguishing substrate affinities.

- 8380 SPECIFICITY OF THE INHIBITORY EFFECTS OF SUGARS ON INTESTINAL AMINO ACID TRANSFER. (E.) Bingham, J. K. (U. Sheffield, England), H. Newey and D. H. Smyth. *Biochim. Biophys. Acta* 120(2):314-316, 1966.

Experiments carried out with sacs of everted intestine from unfasted rats showed that sugars such as D-galactose, 3-o-methyl-D-glucose and α -methyl-D-glucoside, which are actively transported and not metabolized, inhibited intestinal transfer of both methionine and proline. This inhibition is reduced in the presence of glucose. Glucose alone, which is actively transferred and metabolized, stimulated proline transfer but not methionine transfer. Intestinal transfer of these 2 amino acids was unaffected by fructose, mannose, sorbose, rhamnose, 2-deoxyglucose, lactose and mannitol. These substances are not actively transported in the intestine, but some are metabolized there; thus, the above-mentioned inhibition seems to be due to competition for some common requirement involved in active transfer.

- 8381 ABSORPTION OF MEDIUM-CHAIN LIPIDS FROM THE RAT CECUM. (E.) Valdivieso, V. D. (Harbor Gen. Hosp., Torrance, Cal.) and A. D. Schwabe. *Am. J. Dig. Dis.* 11(6):474-479, 1966.

Lipid absorption was estimated by continuous monitoring of expired $C^{14}O_2$ for 1 hr. in male albino rats following intracecal admin. of C^{14} -labeled octanoic acid (specific activity = 13.7 mc/mmmole before dilution) or glyceryl trioctanoate (specific activity = 3.0 mc/mmmole). An av. of 13.6% of the admin. dose of octanoic acid was recovered as $C^{14}O_2$; the rate of recovery was not affected by thorough washing of the cecum prior to instillation. An av. of 9.8% of the admin. dose of glyceryl trioctanoate was recovered as $C^{14}O_2$; recovery was reduced to 0.7% by prior washing of the cecum. Thin layer chromatography revealed the presence of detectable amounts of mono- and diglycerides when samples of cecal contents were aspirated at 20, 40, and 60 min. after trioctanoate instillation. Results indicate that significant amounts of octanoic acid and glyceryl trioctanoate can be absorbed from rat cecum. While absorption of medium-chain fatty acids seems to proceed independently of luminal factors, the absorption of trioctanoate seems to be almost entirely dependent upon intraluminal factors, which are capable of hydrolyzing this fat to lower glycerides and octanoic acid.

- 8382 EXCRETION OF FAT AFTER VAGOTOMY ALONE AND IN COMBINATION WITH PYLOROPLASTY: AN EXPERIMENTAL STUDY. (E.) Wastell, C. (Westminster Sch. Med., London). *Brit. Med. J.* 1(5497):1198-1199, 1966.

Fecal fat excretion was measured in adult mongrel dogs subjected to various surgical technics commonly used in the treatment of chronic duodenal ulcer. A slight,

ABSORPTION

but not significant, increase in mean fat excretion (g/24 hr.) was observed following total vagotomy (0.31 before and 0.5 after) or anterior selective vagotomy (0.74 before and 1.07 after) alone. Marked increase in mean fat excretion, however, was observed in animals subjected to pyloroplasty alone (0.99 before and 2.61 after) or in combination with anterior selective vagotomy (0.93 before and 3.82 after). In animals subjected to laparotomy alone, mean fecal fat excretion remained constant before (0.57) and after (0.58) surgery. It is concluded that the increased fecal fat excretion observed after pyloroplasty is due to the fact that the pylorus accepts much larger fragments of food and conducts them into the duodenum before adequate reduction in size, resulting in decreased absorption.

383 RESORPTION OF POLYPHOSPHATES. (Ger.) Fingerhut, M. (U. Mainz, Germany), F. Ruf and K. Lang. Zschr. Ernaehrungswiss. 6(4):228-241, 1966.
 up to 16 hr. after rats received P³²-labeled tetrasodium diphosphate, pentasodium triphosphate or sodium polyphosphate-64 by esophageal sound, radiometric and paper chromatographic studies of protein-free, complete blood showed the presence of radioactive, inorganic orthophosphate and adenosine orthophosphoric acid, alone, indicating that only orthophosphate was resorbed, following enzymatic breakdown of the polyphosphates in question. The authors comment that the amount of orthophosphate resulting from degradation of orally admin. polyphosphates and thus made available for resorption is a function of the degree of condensation and becomes progressively less as the length of the chain increases. They conclude that orally admin. polyphosphates are not toxic themselves, inasmuch as only the orthophosphate resulting from their enzymatic breakdown is actually resorbed into the system.

384 POLYPHENOLIC COMPOUNDS AND INTESTINAL TRANSFER. (E.) Hand, D. W. (U. Sheffield, England), P. A. Sanford and D. H. Smyth. Nature (London) 209(5023):618, 1966.
 The effect of polyphenolic compounds on the intestinal transfer of glucose (28 mM) and methionine (15 mM) was studied in everted rat small intestine (middle fifth of the combined jejunum and ileum) sacs. Glucose transfer was markedly inhibited by phlorrhizin at conc. of 5×10^{-5} M and nearly abolished by conc. of 5×10^{-4} M; phloretin caused little inhibition at conc. of 5×10^{-5} M but marked reduction at 5×10^{-4} M; phenolphthalein (5×10^{-5} M) had the same effect as equimolecular conc. of phlorrhizin; phenol red had little effect even at conc. of 5×10^{-4} M. When glucose was present initially in the serosal fluid, phenolphthalein (5×10^{-5} M) did not affect glucose disappearance and had slight, if any, effect on fluid transfer. However, phloretin reduced fluid transfer from 2.3 to 0.4 ml, indicating impaired glucose metabolism. Phenolphthalein inhibited methionine transfer at conc. of 5×10^{-5} M, while much greater quantities of phlorrhizin were required to cause similar inhibition; phenol red (1×10^{-4} M) had no effect on methionine transfer; phloretin (5×10^{-4} M) had a greater effect on methionine transfer than phlorrhizin in the same conc.

385 REACTION OF ISOLATED JEJUNAL ABSORPTIVE EPITHELIAL CELLS TO DRUGS. (E.) Mohiuddin, A. (U. Lagos Sch. Med., Nigeria) and G. O. Olubi. Anat. Anz. 118(4):405-412, 1966.
 The natural fat absorptive capacity of jejunal villi epithelial cells (taken from fasting rats) was stimulated in the presence of acetylcholine, pilocarpine, histamine and serotonin. While the stimulation induced by the latter three drugs was similar, that brought about by acetylcholine was noticeably greater. The excised jejunal segments were incubated for 90 min. with the drugs in a medium which consisted of Tyrode's soln. with glucose plus an innocuous emulsion of fat (vol., 1:30). After incubation with acetylcholine, fat was detectable in the epithelium from the tips down to the stems. There was less fat with the other drugs, and less still when no drug was present. Cells which have been isolated by scraping the villi continue to demonstrate a capacity for fat absorption which was also stimulated by these same drugs, acetylcholine being the most effective.

386 A RAPID QUANTITATIVE METHOD FOR MEASURING INTESTINAL ABSORPTION OF VITAMIN B₁₂ IN MAN USING A DOUBLE LABEL HEPATIC UPTAKE TEST. (E.) Weisberg, H.

(New York Coll. Med., N. Y.) and G. B. Jerzy Glass. J. Lab. Clin. Med. 68(1):163-172, 1966.

Radioisotope-labeled B₁₂ was admin. orally (0.5 µg Co⁶⁰B₁₂) and simultaneously inj. i.v. (0.1 µg-0.05 µg Co⁵⁷B₁₂). Hepatic uptake was measured by counts using a sodium iodide crystal detector with proper instrumentation. All counts were corrected in vivo for the different counting characteristics of the two isotopes. The final formula is:

$$\text{Intestinal absorption (\%)} = \frac{(\text{Co}^{60} \text{ hepatic counts})}{1230 + 0.53 (\text{Co}^{57} \text{ hepatic counts})} \times 100$$

The double label method successfully indicated the percentage absorption in patients with liver disease because the counts were proportionately lower for the oral and inj. isotopes. For similar reasons problems of liver geometry and size, and individual variations in thickness of s.c. fat were cancelled out. At 7-10 days mean intestinal absorption was 72.2% and 72.8% using i.v. tracer doses of 0.1 and 0.05 µg, resp., in 2 groups of 10 normal subjects each; 71.6% in 10 patients with liver disease, and 49.0% in 25 patients who had subtotal gastrectomy. It was 4.4% in 10 patients with pernicious anemia after B₁₂ alone, and 49.8% after repeat admin. of B₁₂ with 1 N.F. unit of hog intrinsic factor concentrate. In 31 patients for whom B₁₂ absorption was calculated at 48 hr. (after removal of unabsorbed B₁₂ from the intestinal tract) the results were virtually the same as at 7-10 days. The advantages of the double label method are that it avoids the difficulties of complete stool and urine collections; it is independent of patient cooperation and hepatic or renal function; it also yields strictly quantitative results within 48 hr.

SECRETION

- 393 REGIONAL CONTRIBUTIONS TO PORTAL BLOOD HISTAMINE IN THE DOG. (E.) Rutherford, R. B. (Johns Hopkins U. Sch. Med., Baltimore, Md.), B. Mehman and R. D. Brickman. Surgery 60(1):159-170, 1966.
- Regional contributions to portal blood histamine were studied in 40 dogs of either sex and mixed breed by 2 methods: diversion of venous return from individual regions of the gastrointestinal tract, and the use of chronic indwelling sampling catheters in the portal vein and its major tributaries. Diversion of portal flow into the inferior vena cava caused a definite rise in histamine in arterial plasma after a protein meal. Most of the postprandial increase in blood histamine was contributed by the ileum and jejunum. In the Eck fistula group, fasting histamine levels were not elevated in shunted dogs unless liver function deteriorated. These data do not establish the role of histamine as the cause of post-shunting hypersecretion but they strengthen the possibility. Some as yet unknown secretagogue with the same regional distributions and contributions may be involved. If histamine is responsible, the mechanism is more complex than simply the elevation of circulating levels of histamine.
- 394 HEIDENHAIN POUCH HYPERSECRETION AFTER INTRADUODENAL INJECTION OF PANCREATIC JUICE. (E.) White, T. T. (U. Washington Sch. Med., Seattle), G. Stacher and J. P. T. Tea. Surgery 60(1):107-110, 1966.
- Pancreatic secretion was studied in 19 dogs (wt. 10-15 kg) with denervated gastric (Heidenhain) pouches. The secretory response of the pouch to feeding before and after formation of a total pancreatic fistula was measured in animals of Group 1; the vol. and total acid content of gastric secretions were determined under controlled conditions. Pouch secretion decreased 43.5% in vol. and 61% in total acid after construction of the fistula. Results are statistically significant. In animals of Group 2, 30-50 ml of pancreatic juice was inj. into the duodenum. This caused increased gastric secretion in both eating and fasting animals. In dogs stimulated by eating, gastric vol. rose from an hourly mean of 12.6 to 15.6 ml and acid rose 2.5 to 3.72 mEq after duodenal inj. of pancreatic juice. Fasting dogs showed a similar increase in rate of gastric vol. and acidity after inj. of pancreatic juice into the duodenum. Mild alkali (Tris buffer or aluminum hydroxide gel) was inj. into animals of Group 3; a significant increase of gastric acid occurred only in animals stimulated by eating. It is possible that increased gastric acid (and also gastric motility) observed in these experiments may be mediated through release of duodenal gastrin, or by depression of a gastric inhibitory mechanism.
- 395 COMPARISON OF THE EFFECT OF 2-DEOXY-D-GLUCOSE AND INSULIN ON GASTRIC ACID SECRETION IN DOGS. (E.) Eisenberg, M. M. (VA Ctr., Los Angeles, Cal.), G. S. Emäs and M. I. Grossman. Surgery 60(1):111-117, 1966.
- The effect of 2-deoxy-D-glucose (I) on gastric acid secretion was studied in 6 adult mongrel dogs with gastric fistulas before and after total bilateral thoracic truncal vagotomy. The stimulatory effect of I was abolished after vagotomy. Dose response curves to I and insulin were established in dogs with gastric fistulas (innervated) and Heidenhain pouches (denervated). I had an earlier onset and higher peak 15-min. outputs of gastric juice. With the gastric fistula proximal to the pyloric portion of the stomach, acid was diverted from both the antrum and duodenum. Closure of the gastric fistula allowed the acid to bathe the antrum and enter the duodenum, thus abolishing the response of the vagally denervated pouch to both I and insulin. Gastric secretion from fistulas and Heidenhain pouches stimulated by submaximal doses of histamine was augmented by I. This is interpreted as caused by vagal stimulation of oxyntic glands plus vagal release of gastrin. Insulin inj. after histamine stimulation produced varying effects depending upon the dosage, status of innervation of fundic glands, and the presence and character of the background secretion.
- 396 EFFECT OF SECRETIN ON INSULIN SECRETION. (E.) Unger, R. H. (U. Texas Southwest. Sch. Med., Dallas), H. Ketterer, A. Eisentraut and J. Dupré. Lancet 2(7453):24-26, 1966.

SECRETION

The effects of both crude (obtained from hog duodenal mucosa) and highly purified secretin preparations (containing 1.0 U/mg and 15 U/ μ g of secretin, resp.) on insulin secretion were studied in anesthetized mongrel dogs following inj. into the pancreaticoduodenal vein in the direction of blood flow. Within 1-3 min. following inj. of crude extract, a more than 3-fold rise in mean plasma conc. of insulin in the pancreaticoduodenal vein was observed. The rise appears not to be the result of a change in pancreatic blood flow. Purified secretin gave similar results, suggesting that it is the active component of the crude extract. The response of insulin secretion to secretin is not accompanied by arterial hyperglycemia. In this respect and also in rapidity of onset the response differs from that of insulin to glucagon (See also no. 8397.)

- 8397 EFFECTS OF SECRETIN ON INSULIN AND GLUCAGON IN PORTAL AND PERIPHERAL BLOOD IN MAN. (E.) Dupré, J. (Royal Victoria Hosp., Montreal, Canada), L. Rojas, J. J. White, R. H. Unger and J. C. Beck. Lancet 2(7453):26-27, 1966.

The effects of i.v. admin. of crude or purified secretin (approx. 0.5-1.0 U/kg over 60-90 second) were studied in 10 patients in whom portal venography and manometry were undertaken for investigation of cirrhosis (5) or carcinoma (5) of the liver. The purified preparation, containing no glucagon and only traces of immunoreactive insulin, was inj. into 4 subjects; crude secretin was admin. to 6. Conc. of glucose, immunoreactive insulin, and glucagon were determined in peripheral and portal blood. A large rise in insulin conc. in portal blood and a smaller rise in peripheral blood were observed after secretin admin. Changes in glucose and glucagon conc. were not significant. The response to the two different preparations of secretin were indistinguishable and were not affected by the route of inj. of the test dose. The rapid release of insulin suggests that the response is not mediated by circulating glucagon, but an effect on the release of glucagon within the islets cannot be excluded. Results show that secretin stimulates the release of insulin from the pancreas. It can be concluded that secretin is capable of producing some, if not all, of the features which distinguish the response to ingested glucose from that to glucose admin. i.v. (See also no. 8396.)

- 8398 EFFECT OF ELECTRICAL STIMULATION OF THE RETICULAR FORMATION ON GASTRIC SECRETORY ACTIVITY. (E.) Pradhan, A. C. (Burla Coll. Med., Sambalpur, India), T. C. Gupta and R. N. Sen. Indian J. Med. Res. 54(3):246-255, 1966.

Marked increase in the volume, acidity (free and total) and pepsin content occurred in gastric juice which was collected from innervated dog gastric pouches after stimulation of medial parts of the midbrain and medullary reticular formation. Stimulation of other parts of the reticular formation also produced these increases but to a lesser extent. Max. increase in pepsin content was seen after stimulation of the lateral midbrain reticular formation. After the second or third day of stimulation of the medial parts of midbrain and the medullary reticular formation, frank hemorrhage and acute stomach ulcers developed in both the pyloric regions and the gastric pouches. Erosion of the gastric mucosa and occult blood in the gastric juice followed stimulation of the medial parts of caudal medullary reticular formation.

- 8399 SUPERETHERIFIED FAT AS A STIMULATOR OF PANCREATIC SECRETION. (Rus.) Sysoev, Iu. A. and L. S. Fomina. Vop. Pitan. 25(1):49-55, 1966.

Pancreatic secretion was investigated in dogs bearing pancreatic duct fistulas fed high doses of superetherified pork or beef fat or the corresponding untreated fat in single (Group 1) or repeated (Group 2) admin. The quantity of pancreatic juice was 2-4 times lower after natural pork or beef fat feeding than after meat feeding. Hourly secretion rates were similar during natural pork or beef fat feeding. Trypsin, amylase, and especially lipase conc. were greater after natural fat feeding than after meat feeding. Secretion of pancreatic juice after superetherified pork fat feeding was higher and lipase conc. lower than after natural pork fat feeding; lipase conc., however, was still higher than after meat feeding. The lipase:amylase ratio was lower after superetherified than after natural pork

SECRETION

at feeding. Pancreatic juice secretion was less after superetherified beef fat feeding than after natural beef fat or meat feeding; lipase conc. was higher; the ratio of lipase to amylase and trypsin was similar for both beef fat-fed groups but markedly lower than after meat feeding. Dogs of Group 2 received rations containing 60% (by calories) of superetherified or natural pork fat, while controls were fed diets containing a physiologic ratio of nutritional compounds. After natural pork fat feeding, pancreatic secretion was increased, trypsin and amylase conc. was decreased in most cases, lipase conc. was either decreased or increased, and the ratio of lipase to amylase and trypsin was higher than in controls. Secretory changes were less pronounced after natural pork fat feeding than after sunflower oil feeding. Changes were similar after superetherified pork and natural pork fat feeding. It is concluded that superetherification and subsequent deodorization of pork or beef fat has no significant effect on the physiologic characteristics of the fat as a specific stimulant of pancreatic secretion.

400

SECRETION OF α -AMYLASE BY THE EMBRYONIC CHICK PANCREAS IN VITRO. (E.)
Kulka, R. G. (Hebrew U., Jerusalem, Israel) and U. Yalovsky. J. Cell Biol. 29(2):287-292, 1966.

pancreas (isolated together with the duodenal loop) from an 8-day chick embryo was capable of amylase secretion in vitro despite the fact that it is not until day 19 of development that this gland begins to show maturation with distinct biochemical and morphologic changes. Amylase secretion was greater in the 12-day embryo and the rates of secretion continued to increase with developmental age. Measurement of the specific activity in the pancreas and the medium clearly showed that the amylase was secreted and had not resulted from a nonspecific leakage of cell content. Secretion was stimulated with carbamylcholine in all cases and could be blocked by atropine or anaerobiosis which again indicates an active, energy-requiring process. Where it was necessary to remove the pancreas with a duodenal loop (embryo under 12 days), it was shown that these loops contained no amylase.

401

PARTICIPATION OF THE CEREBRAL CORTEX AND THE OPTIC THALAMUS IN THE ORGANIZATION OF FOOD-CONDITIONED AND UNCONDITIONED REFLEXES. (Rus.)
Gavrilova, L. N. (USSR Acad Med. Sci., Leningrad). Zhur. Vyssh. Nerv. Deiat. Pavlov 16(1):225-232, 1966.

In 2 dogs with exteriorized tongue parts and ducts of both parotid glands, unconditioned and conditioned reflexes were studied following electrical stimulation of the skin of the left thigh, application of 0.1 N HCl to the left side of the tongue, metronome sound, and feeding of 20 g of a mixture of meat and dry bread powder. In dogs subjected to left thalamus ablation, left acid-conditioned reflexes were absent at the beginning of the experiment and appeared only on the left side after the third application on electrical impulse; left acid unconditioned reflexes varied between 170-230 scale divisions (1 scale division = 0.01 ml). Right parotid gland secretion under the effect of conditioned and unconditioned stimulation amounted to 80-115 scale divisions following irradiation of cerebral hemispheres from left to right. Food-conditioned reflexes on the side of thalamus ablation were less than those on the intact side. Conditioned secretion and unconditioned reflexes on the left (ablation) side were 10-15 and 285-315 scale divisions, resp.; on the right side, values were 25-55 and 340-370 scale divisions, resp. Electro-corticograms in dogs with unilateral thalamus ablation were asymmetrical; background activity on the left side was markedly less in amplitude and frequency than on the intact side. Section of the corpus callosum failed by day 6 to affect secretion, i.e. the quantity secreted was the same for both the left and right glands and the electrical activity of the hemispheres remained unchanged. Following removal of the right orbital region of the cerebral cortex, no difference was observed in secretion patterns of the left parotid gland after 2 mo.; at the same time, conditioned reflexes on the right side were almost completely absent and unconditioned reflexes decreased from 340-370 to 50-60 scale divisions. Histologic studies of the brain showed damage to nuclei of the optic thalamus. On the side of the thymus ablation, structural changes of the frontal, temporal, parietal, occipital, and limbic region were observed; no cell prolapse was observed on the intact side.

SECRETION

- 8402 EFFECTS OF THE AVAILABILITY OF BILE ON PANCREATIC EXOCRINE SECRETION. (Ger.) Vogel, G. (Madaus Inst. Biol., Cologne, Germany), W. Grott and M. Kürten. Pfluger Arch. Ges. Physiol. 288(2):103-108, 1966.

In rats bearing choledochoduodenal, choledochojunal or choledoch ileal anastomosis it was found that the more aboral the region in which bile was first made available in the intestine, the greater was the rate of pancreatic exocrine secretion. The max. increase recorded, as compared to controls, was 46% when the bile was introduced into the ileum. This, in turn, was approx. equal to the effect of stopping bile flow entirely by ligating the common bile duct, although it resulted in less increase of protein conc. in pancreatic exocrine secretion. Protein conc. reached 19% when the duct was ligated, with a total increase of 58% in pancreatic protein excretion as compared to controls. It is concluded that the flow of endogenous bile inhibits pancreatic exocrine secretion instead of stimulating it, with a progressive increase of the degree of inhibition the higher the region in which bile is available in the intestinal tract.

- 8403 EFFECTS OF CONDITIONING AND THE TYPE OF FOODSTUFFS ON ACTIVATION OF GASTRIC HISTIDINE DECARBOXYLASE. (Fr.) Garbarg, M. (Broussais Hosp., Paris), G. Pelletier and B. N. Halpern. C. R. Soc. Biol. (Paris) 159(12) 2312-2317, 1965.

In rats, a somewhat modified repetition of Pavlov's experiment which demonstrated conditioning in dogs failed to result in gastric activation of histidine decarboxylase in response to a stimulus associated with feeding over a period of 2 wk.; rapping on the animals' cage before introducing the feed. The greatest degree of activation achieved after introducing nutrients by gastric sound followed admin. of a standard rat-food preparation or beef serum albumin; moderate degrees of activation followed the introduction of olive oil or alcohol; at least some demonstrable degree of activation followed the introduction of caffeine, starch or histamine (the latter admin. s.c.). Water failed to activate the enzyme. The authors suggest that activation of the enzyme may result from distention of the gastric wall with a consequent initiation of the digestive process, even though gastric secretions have no effect on the substance introduced into the stomach.

- 8404 CARBON DIOXIDE METABOLISM IN THE INTACT MAMMALIAN STOMACH. (E.) Miyagi, S. (Albany Med. Coll., N. Y.), C. P. Shoemaker, Jr. and S. R. Powers, Jr. Surgery 59(6):1083-1091, 1966.

A technic is described for the total collection and continuous measurement of gastric venous blood flow and for the *in vivo* determination of the relation between acid production, O_2 consumption, and CO_2 utilization in the intact mammalian stomach. In Group 1, CO_2 metabolism was studied by measuring corresponding arterial-gastric vein gradients in 8 dogs during a resting or nonstimulated state; in Group 2, CO_2 and O_2 metabolism was studied by the same method in 10 dogs before and during acid secretion; in Group 3, CO_2 and O_2 metabolism was studied before and during acid secretion in 9 dogs using the same method as above and by measuring the total gastric venous outflow. In Group 1, it was found that the CO_2 content of venous blood was less than that of arterial blood. In Group 2, when significantly elevated levels of acid production were observed after admin. of histamine, the arterial pH was within fairly narrow range; high levels of acid secretion were associated with a progressively more alkaline pH in the gastric venous blood. In Group 3, the amount of CO_2 in arterial blood was greater than that in gastric venous blood, whereas, during the period of active acid secretion, the amount of total CO_2 in the gastric venous blood was significantly in excess of that produced by gastric metabolism. It is suggested that the resting stomach removes and stores CO_2 from arterial blood, and that during periods of acid secretion, this stored CO_2 is utilized to form carbonic acid, with release of H^+ ions into the gastric cell and discharge of bicarbonate ions into the gastric veins.

- 8405 LONG-TERM ANTICHOLINERGIC ADMINISTRATION AND GASTRIC SECRETORY FUNCTION IN DOGS. (E.) Posey, E. L., Jr. (U. Mississippi Sch. Med., Jackson), R. Elliott, J. Aldridge, C. Turner and H. Franklin. Am. J. Dig. Dis. 11(6):421-431, 1966.

SECRETION

daily peroral admin. of glycopyrrolate for a period of 11 wk. resulted in progressive diminution of gastric acid secretion in both intact dogs and dogs bearing Heidenhain pouches. The percentage diminution at the end of the period was 94 and 83, resp. The effect was spontaneously reversible in both groups over a period of 4 wk. following withdrawal of the anticholinergic. Serial pouch and mucosal biopsies showed no significant changes when examined by light and phase microscopy. However, in another group of intact animals undergoing similar anticholinergic treatment, the mean parietal cell count at the end of wk. 11 was reduced from $0.61-0.669 \times 10^9$. Under ultramicroscopy, approx. 1 cell in 4 showed collapse of intracellular canaliculi and marked dilatation and granulation of the endoplasmic reticulum. Whether these changes were drug-induced or due to chance could not be determined definitively, because of the small number of animals in both the treated and the control groups involved.

- 406 INHIBITION BY SUGARS OF HISTAMINE-INDUCED GASTRIC SECRETION. (E.) Adamkiewicz, V. W. (U. Montreal Sch. Med., Canada) and P. J. Sacra. Arch. Int. Physiol. 74(1):21-24, 1966.

Male Sprague-Dawley rats fasted for 12 hr. received s.c. inj. (2 ml/100 g body wt.) of 6 mM glucose, sucrose or urea or 3 mM NaCl. Histamine phosphate (1 mg/100 g body wt.) was inj. i.m. 2.5 hr. later. Rats were decapitated 30 min. after the histamine inj. Glycemia was determined by the oxidase-peroxidase enzymatic method. The stomachs were ligated, removed, fragmented and placed for 1 hr. in 100 ml of 0.20. Acidity was determined by titrating with 0.01 N NaOH. Admin. of glucose resulted in hyperglycemia, but had no effect on gastric secretion or acidity. Histamine alone increased both gastric secretion and acidity and produced moderate glycemia, which was significantly inhibited by the admin. of glucose or sucrose; urea and NaCl exerted no inhibitory effect.

- 407 INTRINSIC-FACTOR ANTIBODIES IN GASTRIC JUICE OF PERNICIOUS-ANAEMIA PATIENTS. (E.) Fisher, J. M. (Stanford U. Sch. Med., Palo Alto, Cal.), C. Rees and K. B. Taylor. Lancet 2(7454):88-89, 1966.

Samples of gastric juice from 14 patients with pernicious anemia, 6 patients with biopsy-proven chronic atrophic gastritis, and 6 normal controls were tested for intrinsic factor inhibition activity using a special modified Ardeman-Chanarin technique. None of the gastric juices from controls or patients with gastritis significantly blocked the inhibition of intrinsic factor-B12 binding by serum intrinsic factor antibody. Intrinsic factor inhibitor was found in the gastric juice of 5 of the 14 pernicious anemia patients; of these, 4 had serum intrinsic factor antibodies also and 1 did not. In 5 of 9 pernicious anemia patients whose gastric juice did not inhibit intrinsic factor, serum intrinsic factor antibodies were present. The data suggest that the intrinsic factor inhibitor detected in the gastric juice of some patients with pernicious anemia is an antibody which is specific for intrinsic factor and does not inhibit other B12 binders.

- 408 EFFECTS OF HISTAMINE, FEEDING, AND INSULIN HYPOGLYCEMIA ON NET IONIC FLUXES IN GASTRIC POUCHES. (E.) Wlodek, G. K. (McGill U., Montreal, Canada) and R. K. Leach. Arch. Surg. (Chicago) 93(1):175-181, 1966.

Pavlov fundic pouches with stainless steel cannulas for drainage were prepared in adult dogs. All experiments were performed after a 24-hr. fast. A definite voln. of a standard acidic soln. (0.078 N mannitol containing 100 mEq HCl, 15 mEq NaCl and 10 g polyethylene glycol per liter) was introduced into the pouch. When the soln. was mixed and stabilized with fluid in the pouch, a sample was withdrawn and analyzed for Na, K, Cl, H ion conc. and polyethylene glycol conc. Av. results were obtained by careful determination of secretion before and after 3 types of stimulation: histamine phosphate (10 mg) preceded by 20 mg of diphenylhydramine (Benadryl) i.v.; feeding by mouth; and i.v. inj. of 1.5 U/kg of crystalline zinc insulin. Histamine stimulation caused marked increase in the vol. and in HCl and K net gains; Na net gain was greatly reduced. Food caused greatly increased vol.; HCl and K also increased; Na net gain was decreased. Insulin produced significant increases in vol., HCl, and K with no reduction in the net gain of Na. Results indicate a difference in the mechanism of action of antral and vagal stimulation.

SECRETION

- 8409 HEMODYNAMICS OF PANCREATIC SECRETION. WITH OBSERVATIONS ON PANCREATIC OXYGEN CONSUMPTION. (E.) Eichelter, P. (State U. New York, Buffalo) and W. G. Schenk, Jr. Arch. Surg. (Chicago) 93(1):200-207, 1966.
In dogs, pancreatic secretion peaked at 205% normal levels 2-5 min. after i.v. inj of secretin (0.2 U/kg), accompanied by 71% increase of flow through the pancreatic artery, 28.5% decrease of flow through the abdominal aorta and 60% increase of pancreatic oxygen consumption. The effect lasted 5-10 min., followed by reduction of pancreatic secretion to below pretreatment levels within 15-20 min. The pancreatic arteriovenous oxygen differential remained unaffected throughout.
- 8410 STUDIES ON THE EFFECTIVENESS OF CERTAIN CHOLERETIC AGENTS. (Ger.) Mörsdorf, K. (U. Bonn, Germany) and G. Wolf. Deutsch. Med. J. 17(10): 303-306, 1966.
Male Wistar rats of 220 g were anesthetized with 75 mg/kg aprotobarbital, the hepatic ducts catheterized and samples collected at 30-min. interval, for a max. of 7 hr. The animals were kept at constant temperature and fluid loss was corrected by adm of saline. The fractions were measured for total vol. (in mg), content of solids (mg), bile acid content (in μ g, as cholic and deoxycholic acids together, determined spectrophotometrically after organic solvent extraction), and cholesterol (in μ g, nephelometric determination after precipitation with Digitonin). Four choleretic compounds were tested: Decholin (dehydrocholic acid); Felogen (malonyl-mono- α (2,5 endomethylene- Δ^3 -cyclohexenyl-ethyl ester); Hepalande (methonaphthone); and RW-551A (Rowachol), representing a combination of terpenes, i.e.: menthol:32.0; methone: 6.0; α - and β -pinene:17.0; borneol:5.0; camphene:5.0; cineol:2.0; and olive oil to 100. A dose-related increase was observed with each of the 4 compounds, but results on Felogen and Hepalande, having been found less effective than Decholin, are not reported. Optimal doses for Decholin and for RW-551A are given as 600 mg/kg and 4.0 ml/kg, resp. Decholin increased total vol. from 3,911 mg to 6,449 mg (+65%), whereby a 130% increase occurred in the first hr., followed by a steady decrease. RW 551A increased total output to 9,772 mg (+150%), the increase proceeding steadily over the entire experimental period of 7 hr. (max. in one fraction: 200%). Total solids increased from 94 mg to 169 mg (+80%) with Decholin and to 226 mg (+140%) with RW 551A. Bile acids increased from 8,763 μ g to 11,678 (+33%) and 9,634 μ g (+10%), resp. Cholesterol excretion was increased by Decholin from 248 μ g to 348 μ g (+40%), but decreased to 147 (-41%) by RW 551A. The difference in the action of the two drugs, i.e. max. effect of Decholin reached in the first hr. followed by a steady loss of effectiveness as compared to the increasing and lasting effect of RW 551A. The data are preceded by a review of drug therapy in various biliary conditions, with the mention of a very large number of well known and routinely used drugs.

DIGESTION

- 416 CHANGES IN THE ENZYMATIC ADAPTATION OF GASTRIC GLANDS DURING THE ACTION OF PROTEIN HYDROLYSIS PRODUCTS ON THE MUCOSA OF THE SMALL INTESTINE. (Rus.) Sabsai, B. I. (USSR Acad. Med. Sci., Moscow). Biull. Eksp. Biol. Med. 61(2):17-21, 1966.

Enzymatic changes in the gastric glands were studied in 5 dogs with intestinal fistulas (4 with gastric fistula and 1 with a Heidenhain pouch). In most animals, the inj. of protein hydrolysis products into the terminal portion of the ileum during gastric secretion induced by meat feeding caused increased digestion of animal (muscle) proteins; inj. into the median portion of the jejunum produced no significant changes. Digestion of vegetable protein (gluten) remained unchanged. Similar changes were observed after admin. into the intestinal fistulas of different protein hydrolysates (chymus from the jejunum of a donor dog, products of the enzymatic hydrolysis by gastric and pancreatic juice of meat protein, and peptone soln.), although changes induced in protein digestion by the last 2 were not statistically significant. The inj. of peptone soln. into the terminal ileum of the dog bearing Heidenhain pouch caused increased digestion of gluten and decreased digestion of meat protein by the gastric juice in most animals. The inj. of protein hydrolysate into an extensively resected intestine caused a further increase in variations of the correlation between proteolytic activity to muscle protein or gluten after surgery. Changes in the enzymatic adaptation of gastric glands depend to a certain extent on the degree of hydrolysis of protein compounds entering the intestine. The admin. of less hydrolyzed products causes greater changes, while the admin. of more hydrolyzed products produces less pronounced changes. Changes may also be due to the qualitative characteristics of chymus and the rate of its supply to the lower part of the small intestine.

- 417 INHIBITORY ACTION OF GLUCIDES ON TRYPSIN ACTIVITY. (E.) Kerekes, M. F. (Rumanian Acad. Sci., Tirgu Mures). Nature (London) 210(5036):633, 1966. Arabinose, D-glucose, D-galactose, D-mannose, D-fructose, maltose and saccharose (1 M soln. except for the disaccharides which were 0.5 M soln.) all showed some inhibitory action on trypsin activity on azocasein. The strongest inhibitory effect (54.4%) was seen with galactose. There was no correlation between the inhibitory effect and the sugars' solubility, but except for galactose and arabinose, the inhibition correlated with the size of glucidic molecules. This inhibition seems to be a non-specific retardation due to steric interference and is not to be confused with competitive inhibition.

- 418 THE PROTEASES, AMYLASE AND LIPASE OF THE PANCREAS AND INTESTINAL CONTENTS OF GERM-FREE AND CONVENTIONAL RATS. (E.) Lepkovsky, S. (U. California, Berkeley), F. Furuta, K. Ozone and T. Loike. Brit. J. Nutr. 20(2):257-261, 1966.
- A little difference was found between the conc. of proteases, amylase and lipase of the pancreas and corresponding intestinal, cecal and colonic contents of female germ-free and conventional rats. Bacterial activity was evident in the conventional rats as the cecal contents had a greater percentage of protein nitrogen and a lower percentage of nonprotein nitrogen. In both types, the enzyme conc. decreased caudally. The proteases in the intestinal contents of both types were the most stable of the enzymes as comparatively small decreases in its conc. were seen as the intestinal contents passed from the small intestine to the cecum and colon. Amylase was the least stable and lipase stability was intermediate between the other two.

- 419 CARBOXYLIC ESTER HYDROLASES OF RAT PANCREATIC JUICE. (E.) Mattson, F. H. (Procter & Gamble Co., Cincinnati, Ohio) and R. A. Volpenhein. J. Lipid Res. 7(4):536-543, 1966.
- Ethyl butyrate, triolein, 2,3-dioleoyl butane and cholesteryl linolenate were hydrolyzed by lyophilized rat pancreatic juice under various conditions in order to characterize the enzymes in pancreatic juice that hydrolyze nitrogen- and phosphorus-free esters of fatty acids. Three enzymes were established: glycerol-ester hydrolase or lipase, sterol-ester hydrolase and, a third one (unnamed) which hydrolyzes water-

soluble esters. The first enzyme hydrolyzes water-insoluble esters of primary alcohols at an oil/water interface, with a broad pH optimum of 7.5-9.5. It is inhibited by bile salts at pH 8. The second enzyme hydrolyzes esters of secondary and other alcohols at an optimum pH of 8 and it, as well as the third enzyme, requires bile salts. The third is differentiated from the second by its stability at pH 4 and optimum pH of 9.

- 8420 **INTESTINAL DIPEPTIDASES: CHARACTERIZATION, DEVELOPMENT AND DISTRIBUTION OF INTESTINAL DIPEPTIDASES OF THE HUMAN FOETUS.** (E.) Lindberg, T. (U. Lund, Sweden). *Clin. Sci.* 30(3):505-515, 1966.

Spectrophotometric assay of the gastrointestinal tract of 11-23-week-old human fetuses revealed the presence of 5 dipeptidase activities: L-alanyl-L-glutamic acid dipeptidase, L-alanyl-L-proline, glycylglycine, glycyl-L-leucine, and glycyl-L-valine dipeptidase activity. The effects of pH and of bivalent metal ions (Co^{++} , Mn^{++} , Mg^{++} , and Zn^{++}) on intestinal dipeptidase activity are reported. Determination of specific activities of intestinal dipeptidases in fetuses of various ages showed that the enzymes were already well developed at the fetal age of 11 wk. Enzyme distribution studies along the fetal gastrointestinal tract revealed low activities in the stomach (except for L-alanyl-L-glutamic acid dipeptidase) and high activities in the small and large intestine. Dipeptidase activity was present in fetal meconium but was very low or absent in meconium from newborn infants. (See also no. 8321.)

- 8321 **DEVELOPMENT OF THE INTESTINAL DISACCHARIDASE AND ALKALINE PHOSPHATASE ACTIVITIES IN THE HUMAN FOETUS.** (E.) Dahlqvist, A. (U. Lund, Sweden) and T. Lindberg. *Clin. Sci.* 30(3):517-528, 1966.

The specific activities of disaccharidase (authors' method) and alkaline phosphatase (modified Bessey-Lowry-Brock method) were determined in various parts of the gastrointestinal tract in 11-23-week-old human fetuses. Enzyme activities were strongest in the small intestine at all stages of development. High enzyme activity was observed in the meconium of both the large and small intestines. The meconium obtained shortly after birth from full-term infants contained none or weak disaccharidase activity, but very high alkaline phosphatase activity. Isomaltase, invertase, maltase Ia and maltase Ib activity were fully developed in the jejunal mucosa before the fetus was 11 wk. old. Trehalase developed between wk. 11-23 of intrauterine life, and at wk. 23 had reached values comparable to those in adult mucosa. Lactase and cellobiase activities were very weak in the fetuses studied, indicating development of these enzymes during the last mo. before delivery. Maltase II and III were not detected. Alkaline phosphatase activity increased significantly during the period studied, but at wk. 23 its activity was still far below that of adults. (See also no. 8420.)

- 8422 **INTESTINAL DIPEPTIDASES. DIPEPTIDASE ACTIVITY IN THE MUCOSA OF THE GASTROINTESTINAL TRACT OF THE ADULT HUMAN.** (E.) Lindberg, T. (U. Lund, Sweden). *Acta Physiol. Scand.* 66(4):437-443, 1966.

The activity of five dipeptidases, L-alanyl-L-glutamic, L-alanyl-L-proline, glycylglycine, glycyl-L-leucine and glycyl-L-valine, was found to be equally low in the stomach and large intestine mucosa. In the small intestine, low activities were found in the mucosa of the proximal duodenum, whereas that of the jejunum and ileum contained high activities. The tests were made from the gastrointestinal specimens removed during surgery from 25 adult humans with such disorders as stomach and duodenal ulcer, stomach cancer, ileus post-gastroenterostomy, terminal ileitis, ulcerative colitis, carcinoid appendicitis and colon cancer. Optimal pH was determined for each dipeptidase and the various effects of bivalent metal ions were tested and compared with those of a previous study using fetal, rat and pig specimens.

- 8423 **INTESTINAL DIPEPTIDASES. III. CHARACTERIZATION AND DETERMINATION OF DIPEPTIDASE ACTIVITY IN ADULT RAT INTESTINAL MUCOSA.** (E.) Josefsson, L. (U. Lund, Sweden) and T. Lindberg. *Acta Physiol. Scand.* 66(4):410-418, 1966.

The activity of five dipeptidases, L-alanyl-L-glutamic acid, L-alanyl-L-proline, glycylglycine, glycyl-L-leucine and glycyl-L-valine, in the mucosa of the rat gastrointestinal tract was determined and characterized by a new spectrophotometric assay

GESTION

thod. The activities were low in the stomach, the cecum and the large intestine. High activities were found along the whole length of the small intestine with the maximum localized in the middle section. The optimal pH determined for each peptidase was consistent with the physiologic conditions known to exist in the small intestine. Although the capacity of the intestine to hydrolyze dipeptides is higher in the pig, the relative specific activity of the various dipeptidases studied did not differ in the two species. The effect on activity produced by bivalent metals was noted.

MOTILITY

- 8434 A NEW PHARMACOLOGICAL ACTION OF EMETINE. (E.) Ng, K. K. F. (U. Singapore). *Brit. Med. J.* 1(5498):1278-1279, 1966.
Emetine (1×10^{-6} to 5×10^{-6} g/ml) blocked both the inhibitory and motor response of the isolated rabbit ileum to sympathetic nerve stimulation without affecting the direct action of norepinephrine. A similar effect was observed on isolated rabbit colon. The effect of emetine is likened to that of neuron-blocking agents. Present experimental results suggest that emetine-induced diarrhea is due to peripheral sympathetic blockage with a preponderance of parasympathetic activity as a consequence. Analogously, the hypotensive effect of emetine is similar to that of drugs such as bretylium and guanethidine which block the release of norepinephrine from the adrenergic nerve endings.
- 8435 OBSERVATIONS CONCERNING THE PROPULSIVE ACTIVITY OF THE JEJUNUM. STUDIES IN CONTINUOUS RECORDING OF THE FLOW OF LIQUID THROUGH A THIRY-VELLA LOOP IN THE WAKING DOG. (Fr.) Bremer, A. (Free U. Brussels, Belgium). *Arch. Int. Physiol.* 74(1):111-122, 1966.
In dogs, when saline soln. was perfused through a Thiry-Vella loop in the jejunum, the flow was normally discontinuous, with the fluid expelled in short spurts, at more or less rhythmic intervals, from the aboral end of the loop. The frequency of these expulsions ranged from 12-17/min. and their volume was variable. Increase of the liquid pressure caused them to occur at somewhat longer intervals and volume was increased concomitantly. Ingestion of a meal was followed by a brief arrest of flow whose renewal was characterized by a significant decrease of volume and increase of the intervals between expulsions. These changes lasted more than 10 min. Admin. of prostigmine, s.c., had a similar but more prolonged effect. Inj. of atropine or hyoscine butylbromide, i.v., increased the overall volume of flow, which became almost continuous as the tonus of the loop was reduced. Blocking of both vagus nerves at the neck had a similar effect. Pain or repetition of the movements through which pain had been previously induced resulted in a prolonged, virtually total arrest of flow. When the dog was petted by someone of whom it was fond, a similar, but brief arrest occurred. Peritoneal irritation also interrupted the flow at first, due to increased tonus. This was followed by prolonged relaxation of the loop, diminution of the force of the expulsions and increase of the rate of flow until it became continuous.
- 8436 THE EFFECT OF EPINEPHRINE AND OF THE SUPINE POSITION ON ESOPHAGEAL PRESSURE RECORDINGS. (E.) Crompton, G. K. (U. Edinburgh, Scotland), S. Merchant and M. E. Schonell. *Am. Rev. Resp. Dis.* 93(5):716-719, 1966.
The measurement of esophageal pressures of 10 normal males in the sitting and standing position gave the following mean values: end-expiratory esophageal pressure, -2.4 cm water, and +2.9 cm water, resp.; while the mean esophageal pressure excursion/mean tidal volume ratio was 4.91 and 8.06, resp. The increase seen in those measurements conducted in the supine position was statistically significant. These values were not changed significantly by a s.c. inj. of epinephrine (0.5 ml of 1:10 soln.), which indicates epinephrine (at this dosage) does not affect the esophageal muscle tone. Measurements were made with a tube-balloon system connected to a spirometer.
- 8437 EFFECT OF CATECHOLAMINES ON SMOOTH MUSCLE MOTILITY AND PHOSPHORYLASE ACTIVITY. (E.) Diamond, J. (U. Michigan Sch. Med., Ann Arbor) and T. M. Brody. *J. Pharmacol. Exp. Ther.* 152(2):202-211, 1966.
In isolated guinea pig taenia coli, phosphorylase a activity is unchanged 15 or 30 seconds after adding epinephrine (6×10^{-7} M), but is significantly increased 2 min. afterwards. Spontaneous motility of the taenia coli is depressed within 15 sec of the addition of epinephrine. Therefore, it would seem that the relaxant effect of epinephrine on taenia coli is not mediated through phosphorylase activation. Using another smooth muscle type, isolated rat uterine segments, this independency is not so clearly delineated as the epinephrine-induced increased phosphorylase a activity occurs while the motility is being depressed.

ILITY

- 8 RELATIONSHIP BETWEEN SMOOTH MUSCLE CONTRACTION AND PHOSPHORYLASE ACTIVATION. (E.) Diamond, J. (U. Michigan Sch. Med., Ann Arbor) and T. M. Brody. J. Pharmacol. Exp. Ther. 152(2):212-220, 1966.

phosphorylase a activity was found to be significantly higher during the spontaneous contractions of isolated guinea pig taenia coli than during the intervals between these contractions. Using a different smooth muscle, isolated rat uterine segments, was shown that phosphorylase a activity also increases with drug-induced contractions. Thus, it appears that contraction per se is associated with increased levels of phosphorylase a in certain smooth muscle. Control phosphorylase a levels (between contractions) were much lower in the taenia coli than in the uterine segments.

- 9 EFFECTS OF CHOLECYSTOKININ PREPARATION ON THE MOVEMENTS OF THE STOMACH AND SMALL INTESTINE. (E.) Nakayama, S. (Okayama U. Sch. Med., Japan) and H. Fukuda. Jap. J. Physiol. 16(2):185-193, 1966.

admin. to dogs of Cecekin Vitrum (1; i.v. 0.5-1 Ivy dog unit/kg), a potent but purified preparation of cholecystokinin, excited movements of the gallbladder, stomach and small intestine. This excitatory effect was not abolished by either atropine or hexamethonium. The motility of the isolated rabbit duodenal loop or excised muscle strip of the dog jejunum was also increased in the presence of 1. However, when the secretion of natural cholecystokinin was stimulated by perfusion of the isolated jejunum with 0.1 N HCl (the gallbladder reached maximal contraction within several min.), no jejunal movements occurred. This would indicate that 1 contains some unknown substance which excites movements of the small intestine and stomach. Since 1 did not cause an increase in blood pressure, this excitatory substance is probably not Substance P.

- 10 SODIUM CONCENTRATION AND THE EFFECT OF ANGIOTENSIN II ON ILEAL SMOOTH MUSCLE. (E.) Blair-West, J. R. (U. Melbourne, Australia) and J. S. McKenzie. Experientia 22(5):291-292, 1966.

Strips of isolated guinea pig ileum were suspended in a medium containing 30 mEq/liter NaCl (added to normal Ringer soln.), the stimulatory action of valine-5-angiotensin II amide was potentiated three-fold. Conversely, when the sodium content of the Ringer medium was decreased the contractile response to angiotensin II also decreased. Similar tonicity established with sucrose did not cause these changes in response. Atropine (10^{-6} g/ml) added to the medium also reduced the contractile response to angiotensin (by 50-70%) and totally abolished the response to acetylcholine and dimethylphenylpiperazinium. However, when this same dose of atropine was added to a medium with a raised sodium conc. (30 mEq/liter), the potency of angiotensin II was increased approximately ten-fold.

- 11 EFFECT OF POLYGLUCIN ON INTESTINAL MOTOR ACTIVITY. (Uk.) Vorobei, A. I. (Inst. Physiol., Acad. Sci. Uk. SSR, Kiev). Fiziol. Zhur (Kiev) 12(2):261-264, 1966.

In experiments on intestinal motor activity in intact rabbits, the amplitude of peristaltic contractions increased from an av. 2.1 mm to 4.7 mm following i.v. admin. of polyglucin (dextran). Simultaneous increase in intestinal tonus was also observed. Similar results were seen in isolated intestinal segments following treatment with 5, 10 or 20 ml/100 ml of Tyrode's soln., although changes were less pronounced and of shorter duration. Following atropinization (3-4 drops of 1% soln./100 ml of Tyrode's soln.) of isolated intestinal segments, dextran increased the amplitude of peristaltic contractions but not the tonus. A decrease in the amplitude of peristaltic contractions was observed in animals treated in vivo with dextran. Thus, dextran acts by other mechanisms besides its effect on the parasympathetic system. Dextran showed no stimulatory effect on the increased intestinal tonus observed during the action of calcium chloride. Dextran increased the energy processes which occur in the smooth muscle of isolated segments of intestine.

- 12 ACTION POTENTIALS OF GANGLION CELLS IN AUERBACH'S PLEXUS IN THE SMALL INTESTINE OF THE RABBIT. (Ger.) Yokoyama, S. (U. Fukushima, Japan). Pfluger Arch. Ges. Physiol. 288(2):95-102, 1966.

in vitro electromyographic studies of isolated segments of rabbit jejunal canal,

MOTILITY

only weak action potentials could be demonstrated in the longitudinal muscle sheath with spiking at 3-5-second intervals, without fasciculation. When the electrode was inserted into ganglion cells of Auerbach's plexus, spontaneous, rhythmic outbursts of spiking potentials of much greater amplitude were seen at 15-25-second intervals. The frequency and number of spikings in each fasciculation period varied markedly. A small, relatively protracted, negative wave frequently preceded appearance of the first large spiking potential in a given fasciculation period, while the last spiking was followed invariably by a more protracted, positive wave. In specimens which were immersed in oxygen-saturated Tyrode soln., interruption of the oxygen supply resulted in complete disappearance of action potentials, which reappeared after oxygen was restored. Action potentials also disappeared when hexamethonium was introduced into the soln. The fact that the rhythmic appearance of fasciculation periods paralleled a macroscopically observable, rhythmic segmentation phenomenon in the jejunal canal may indicate that the activity of the ganglion cells of Auerbach's plexus is involved in peristaltic activity.

- 8443 STUDY ON MOTILITY OF PYLORUS AND DUODENAL CAP BY CINEFLUOROGRAPHY. (Japanese) Kogure, T. (U. Tokyo Sch. Med.). Nippon Igaku Hoshasen Gakkai Zasshi (Nippon Acta Radiol.) 25(8):958-990, 1965.

Cineroentgenographic studies on pyloric motility were carried out in 121 subjects (total observations 868), of whom some were normal and some had gastric ptosis or duodenal ulcer. At the time of gastric emptying, pyloric motility was "antral-systolic" in all normal and gastric ptosis cases, but not in those with duodenal ulcer. In some cases, peristalsis reached the vicinity of the pyloric ring, but in no case did it actually reach the pyloric ring. In normal subjects, part of the contrast medium was retained in the pylorus at the later phase of contraction. Normal subjects had a longer final phase of contraction than did patients with gastric ptosis, but the overall length of time required for the entire pyloric motility process did not differ. The principal mode of contraction of the duodenal cap was centripetal; in duodenal ulcer patients, mid-section spasm, specific contraction, and pseudodiverticular contraction were also observed. A harmonious pattern of pyloric motility, opening and closing of the pyloric ring, duodenal cap motility, and opening and closing of the apex of the duodenal cap was observed in normal patients; lack of harmony was observed in some patients with gastric ptosis and in many with duodenal ulcer. In normal patients, no reflux from the duodenal cap to the pylorus was observed; in normal and gastric ptosis cases, reflux to the duodenal cap from the upper horizontal and descending portions of the duodenum was seen; in patients with duodenal ulcer, some reflux to the pylorus through the duodenal cap, particularly from the upper descending and horizontal portions of the duodenum, was observed.

- 8444 ESOPHAGEAL MOTOR ABNORMALITIES IN SCLERODERMA AND RELATED DISEASES. (English) Saladin, T. A. (U. Michigan Sch. Med., Ann Arbor), A. B. French, C. J. Zarafonitis and H. M. Pollard. Am. J. Dig. Dis. 11(7):522-535, 1966.

In order to determine the relationship between motor abnormalities and esophageal symptoms, esophageal motor activity was measured by intraesophageal pressure recordings (Code method) in 53 patients with scleroderma and 29 patients with other collagen diseases. Swallowing waves were recorded with the balloon of the apparatus at the cardio-esophageal junction and at several levels in the lumen of the esophagus. Abnormalities in the intraluminal pressure response to deglutition were seen in 42 (79%) of the patients with scleroderma; of these, 26 (62%) also showed diminution or absence of the lower esophageal sphincter pressure zone. Although abnormal swallowing pattern did not correlate with esophageal symptoms, absent cardioesophageal sphincter pressure did. Ten of the 29 patients with other collagen diseases showed similar but less severe abnormalities; in only one of these was the abnormality in the lower esophageal sphincter. Neither abnormality correlated with symptoms in the group. Of the 66 patients who had both X-ray and manometric studies of the esophagus, intraluminal pressure studies showed aperistalsis in all patients without peristalsis on X-ray as well as in 18 patients who appeared to show normal peristalsis on X-ray studies. No significant change was found in the pressure studies after the administration of methacholine to 36 of the patients with scleroderma and abnormal swallowing pattern.

- 45 EFFECTS OF CHANGES IN IONIZATION ON ELECTRICAL ACTIVITY IN THE SMALL INTESTINE OF THE RAT. (Fr.) Rougereau, A. (U. Tours Sch. Med., France) and J. Thouvenot. C. R. Soc. Biol. (Paris) 159(12):2455-2457, 1965.

in vivo studies of basic electrical activity in the rat small intestine, increase the free sodium ion content of the saline bath to above-normal levels resulted in rapid variations of potential in the characteristic slow waves of the external surface, with a tendency to form more angular peaks, occasionally approaching a spiking pattern. Increase of the free potassium ion content increased the amplitude of slow waves initially, followed by increasing irregularity and loss of definition. Increase of the free calcium ion content resulted in progressive obliteration of the slow wave pattern and amplitude, simultaneously, reaching its maximal expression in the form of a somewhat-elevated plateau consisting of a series of rapid oscillations of very small amplitude. The duration of such plateaus was brief (3-7 seconds). Increase of the free magnesium ion content resulted initially in biphasic, alternately negative and positive, sequences, followed by a plateau lasting 6-12 seconds. All these in vivo observations were duplicated in subsequent in vivo studies of rat duodenum, jejunum and ileum. In vivo changes, in response to similar changes of the ionization balance of the environment of intestinal tissue, were similar, but less marked. They were also slower to appear initially and of shorter duration. Increase of the environmental free calcium ion content in vivo induced changes identical to those which have been demonstrated during active absorption of sugars and/or amino acids. Deprivation of free calcium ions (by chelation) resulted in total suppression of spontaneous electrical activity. The authors conclude that active intestinal absorption of sugars or amino acids may require temporary, localized stabilization of membrane polarization, effected by a temporary increase of environmental free calcium ion content to above normal levels. (See also 8446.)

- 46 EFFECT OF PERIODIC VARIATIONS OF LONGITUDINAL TENSION ON THE CONTRACTILE POWER AND TONUS OF SMOOTH MUSCLE IN THE INTESTINE. IN VITRO STUDY IN THE RAT. (Fr.) Rougereau, A. (U. Tours Sch. Med., France) and J. Thouvenot. C. R. Soc. Biol. (Paris) 159(12):2467-2470, 1965.

In vitro studies, smooth muscle from the rat duodenum was strongly resistant to lengthening in response to repeated, cyclic variations of tension; resistance was variable in muscle from the ileum; minimal, in that from the jejunum. Closer study showed alternating zones of strong and weak tonicity in each region, varying in their distribution and apparently corresponding to zones of relatively strong and relatively weak motor-neuron innervation. Zones showing weak motor-neuron innervation appeared to be zones which displayed a type of electrical activity within the tissue which was specifically involved in the absorption process. (See also 8445.)

- 47 ANTI-ACETYLCHOLINE ACTIVITY OF SOME ANTISPASMODICS ON THE GUINEA PIG ILEUM. (E.) Jaju, B. P. (K. G. Coll. Med., Lucknow, India), P. N. Saxena and K. P. Bhargava. Indian J. Med. Sci. 20(4):263-265, 1966.

The maximally effective contracting dose of acetylcholine was determined for guinea pig ileum strips maintained in a modified Tyrode solution bath. Fifty percent of this dose of acetylcholine was repeatedly admin. along with varying doses of anti-spasmodics. The doses of acetylcholine varied from 0.1 to 8 µg/ml. The relative antispasmodic activity relative to atropine (standard) were: pethidine 0.24; papaverine 0.075; neo-octinum 0.069; palerol 0.024; baralgin 0.013; a value was not determinable for novalgin. The mean dose of atropine was 0.000528 mg/100 ml bath. It is suggested that further study of these compounds would be necessary since they may possess a "musculotropic" effect.

- 48 THE MOTOR FUNCTION OF THE STOMACH AND CERTAIN CLINICAL ASPECTS OF EXPERIMENTAL LEAD INTOXICATION. (Rus.) Mambeeva, A. A. (Kazakh Inst. Reg. Path., Alma Ata, USSR). Biull. Eksp. Biol. Med. 61(5):36-40, 1966.

The admin. of lead acetate (20-50 mg/kg/day) resulted in subacute intoxication after 2-77 days in 3 and chronic intoxication after 178-246 days in 4 of 7 dogs with a jejunovaginal fistula. Characteristic clonic-tonic spasm was evident from day 25-45 in animals with subacute intoxication and from 3-6½ mo. in dogs with chronic intoxication. In 2 dogs, normalization of the general state occurred 3 mo. after cessation

MOTILITY

of treatment. Gastric motor function was stimulated in chronic intoxication but depressed in subacute and acute intoxication. In animals with subacute intoxication brief restoration of gastric motor function was followed by depression lasting 2-wk. and subsequent death. In chronic intoxication, initial stimulation of motor function was followed by return to normal and subsequent depression 19-40 days after beginning of treatment. Results establish that the clinical manifestations of experimental lead poisoning in dogs are to a considerable extent similar to those of saturnism in humans.

- 8449 DIFFERENCES IN MOTILITY OF THE UPPER AND LOWER ESOPHAGUS IN MAN AND ITS ALTERATION BY ATROPINE. (E.) Kantrowitz, P. A. (Massachusetts Gen. Hosp., Boston), C. I. Siegel and T. R. Hendrix. Bull. Hopkins Hosp. 118(6):476-491, 1966.

Intraesophageal manometric studies of 6 healthy young men showed a discrete zone of minimal peristaltic pressure lying 5-9 cm below the upper esophageal sphincter and apparently coinciding with the narrow band of purely circular muscle described by Lerche. Highest pressures were found in the middle third of the esophagus; in the lowest several cm, pressures were variable. Atropine, in doses up to 2.0 mg, induced a dose-related decrease of peristaltic pressure below the minimal pressure area, while pressures above it were unchanged. However, in 5 of 6, atropine increased the duration of peristaltic contractions in the upper esophagus and delayed the appearance of peristalsis in the more distal esophagus.

- 8450 TYRAMINE RESISTANT ADRENERGIC MECHANISMS IN THE CARDIA OF THE RABBIT. (Ger.) Wolner, E. (U. Vienna, Austria) and F. Brücke. Naunyn-Schmiedeberg. Arch. Exp. Path. 254(2):91-100, 1966.

The effect of tyramine (I) on the cardiac sphincter of anesthetized rabbits was tested in normal, and bilaterally vagotomized animals under the influence of reserpine, and/or continuous infusions of norepinephrine (II). II infusions (1.0 μ g/kg/min.) could be maintained in vagotomized rabbits for up to 7 hr., in normals for only 3 hr. Reserpine was admin. at 2.5 mg/kg i.m. 48 hr. before experiment, with another 1.5 mg/kg 24 hr. before experiment. I was admin. in single i.v. inj. of 1.0 mg/kg each, repeated at 5-min. intervals. All i.v. inj. and infusions were given into the jugular vein; infusion flow rate of 0.25 ml fluid/min. was never exceeded. Cardiac sphincter pressure was measured manometrically. II had a relaxing effect on the artificial sphincter spasm, produced by vagotomy under all conditions tested; 1.0 μ g/kg resulting in a 25% pressure drop, 2.0 μ g/kg in a 50% drop. Previous reserpine admin. did not alter this effect. Unreserpinized rabbits, however, could not resist a continuous infusion of 1.0 μ g/kg/min. of II for more than 3-4 hr. An initial blood pressure increase of about 30% reverted to normal after 2 hr., i.e. after 120 μ g/kg II, but kept dropping steadily; the rabbits died during hr. 4 of infusion. I, up to 4.0 mg/kg, had no effect on untreated rabbits. The 1.0 mg/kg dose used was ineffective also during the first 2 hr. of II infusion. After 2.5 hr. of infusion it reduced pressure by 10%, after 3 hr. by 20%. A 2nd inj. of I admin. 5 min. after the first had no further effect. Pretreatment of animals with reserpine did not alter the I response. The spasm induced in these cases after reserpine admin. was greatly increased by vagotomy and completely relaxed during subsequent II infusion, which could be continued for 7 hr. in reserpinized rabbits. After discontinuation of infusion the spasm reappeared in 30 min. Inj. of I at this time had a distinct relaxing effect, starting 20-30 seconds after i.v. inj. and lasting up to 3 min. The ratio of the magnitude of I to the length of the preceding infusion of II was rectilinear.

- 8451 MOTOR FUNCTION OF THE STOMACH AFTER EXPERIMENTAL RESECTION. (Rus.) Baziian, R. A. (Inst. Med., Erevan, Armenian SSR). Zhur. Eksp. Klin. Med. Armenian SSR 5(6):41-46, 1966.

HEPATIC METABOLISM

- 52 PRODUCTION OF AUTOANTIBODIES IN RATS IMMUNIZED WITH HOMOLOGOUS OR HETEROLOGOUS LIVER. (E.) Richter, M. (McGill U. Clin., Montreal, Canada), A. U. Sargent, J. Myers and B. Rose. *Immunology* 10(3):211-215, 1966.

selective loss of tolerance in rats to organ-specific hepatic antigens can be induced by immunizing them with either rabbit or rat liver emulsified in complete Freund's adjuvant. The specificity of the rat anti-rat liver and rat anti-rabbit liver antisera for rat hepatocellular antigens was demonstrated by their inability to agglutinate cells sensitized with rat kidney. The specificity of the rat liver antisera reaction with autologous liver was confirmed by fluorescence microscopy. However, cells sensitized with rabbit kidney were agglutinated by the rat anti-rabbit liver sera. Rat and anti-rat liver antisera did not agglutinate cells sensitized with human liver, but did agglutinate cells sensitized with dog, cat and rabbit liver.

- 53 EFFECTS OF ETHIONINE AND GLUCOCORTICOID HORMONES ON CYSTATHIONASE IN THE RAT LIVER. (Fr.) Durieu-Trautmann, O. (U. Paris Sch. Sci., Sorbonne) and F. Chatagner. *Bull. Soc. Chim. Biol. (Paris)* 48(1): 77-88, 1966.

Intact rats of both sexes, a single i.p. inj. of L-ethionine induced considerable increase of hepatic cystathionase activity (I) within a few hr. In adrenalectomized rats, the same effect occurred in the male but not in the female, although adrenalectomy itself exerted no significant effect on I in either sex. In intact rats, single inj. of cortisol increased I slightly, but only in the male. A similar, but somewhat more marked effect, also limited to males, followed single inj. of L-homoserine, while a demonstrable, but statistically non-significant, reduction of enzyme activity followed inj. into adrenalectomized males. It is concluded that the effect of homoserine on I in the male rat is dependent on adrenocorticoid secretion, while the effect of ethionine is not. It is also concluded that, although ethionine loses its effect in adrenalectomized females, the mechanism of action involved in its ability to stimulate I is not dependent on cortisol secretion.

- 54 THE EFFECT OF $1\alpha,7\alpha$ -BIS(ACETYLTHIO)- 17α -METHYLTESTOSTERONE AND $7\alpha,17\alpha$ -DIMETHYLTESTOSTERONE ON PARAMETERS OF LIVER FUNCTION (SERUM ENZYMES, BROMOSULFALEIN RETENTION, COAGULATION FACTORS). (Ger.) Krüskemper, H. L. (U. Bonn, Germany). *Arzneimittelforschung* 16(5):608-612, 1966.

In adult, male volunteers with normal livers, comparable therapeutic and near-toxic doses of $7\alpha,17\alpha$ -dimethyltestosterone inhibited hepatic secretory function to a significantly greater degree than that exerted by $1\alpha,7\alpha$ -bis(acetylthio)- 17α -methyltestosterone, as confirmed by tests of sulfobromophthalein sodium retention, serum transaminase activity and the activity of blood coagulation factors V, VII, X and prothrombin. Neither medication had sufficient effect on coagulation factors to induce disturbances of the overall coagulation process.

- 55 CITRATE METABOLISM BY THE ISOLATED PERFUSED LIVER. (E.) Vang, J. O. (U. Pittsburgh Sch. Med., Pa.), R. Zemel, M. Davidson and T. Drapanas. *Arch. Surg. (Chicago)* 93(1):142-147, 1966.

To confirm the role of the liver in the metabolism of citric acid, the ability of the isolated perfused calf liver to metabolize exogenously admin. citric acid under ideal physiologic conditions is demonstrated employing perfusion of both the hepatic artery and portal vein. It is evident that the metabolism of exogenous citric acid by the perfused liver is slower than citric acid produced endogenously from lactate in blood since only one-half the citric acid load was cleared from the perfusion system within 30 min., while the remainder cleared within 3 hr. Parallel studies showed a lack of increase of blood citrate in the face of rapid clearance of lactic acid and pyruvic acid from the perfusion system indicating that the liver can readily metabolize endogenous citric acid formed in the tricarboxylic acid cycle. No differences in citric acid clearance rates were noted between livers perfused with heterologous (canine) blood and those perfused with autologous blood.

HEPATIC METABOLISM

- 8456 STUDIES ON THE IMPORTANCE OF LECITHIN FOR CHOLESTEROL SOLUBILIZATION IN BILE. (E.) Neiderhiser, D. H. (VA Hosp., Cleveland, Ohio), H. P. Roth and L. T. Webster, Jr. J. Lab. Clin. Med. 68(1):90-102, 1966.

The role of lecithin as a solubilizing agent for cholesterol in bile was investigated in specimens of fresh human (obtained during surgery of patients with biliary disease) or hog gallbladder bile fractionated on Sephadex G-75. Most of the cholesterol and lecithin was eluted at the solvent front. Upon electrophoresis the cholesterol-lecithin complex of this fraction did not show mobility. Mobility similar to that in the original gallbladder bile was restored by the addition of bile salts to a conc. of 0.04 M. The cholesterol complex of hepatic bile does not show electrophoretic mobility. The role of lecithin as a suspending agent for cholesterol was tested by incubating the cholesterol-lecithin fraction with lecithinase. The hydrolysis of lecithin precipitated the cholesterol. The cholesterol in the original fraction was not separated by centrifugation at 100,000 g for 2 hr. The incorporation of additional cholesterol in vitro by gallbladder bile is a function of the amount of lecithin in the bile. The wt. ratio of lecithin to cholesterol approached approx. 4:1 with the incorporation of additional cholesterol.

- 8457 CONTROL OF NICOTINAMIDE-ADENINE DINUCLEOTIDE PHOSPHATE SYNTHESIS IN THE LIVERS OF RATS TREATED WITH ETHIONINE. (E.) Clark, J. B. (U. Coll. London) and S. Pinder. Nature (London) 210(5036):631-632, 1966.

When the amount of ATP in the rat liver is depressed by i.p. inj. of ethionine, the liver shows a greater facility for nicotinamide-adenine dinucleotide (NAD) synthesis than for nicotinamide-adenine dinucleotide phosphate synthesis. A synthesis time study (made in terms of conc. at zero time) showed the following pattern: for NAD, a decrease which began 2 hr. after the inj. of ethionine and reached a minimum of 60% at 4 hr., after which the conc. began to return to normal and was higher in 7 hr. than it had been at 2 hr.; in contrast, for NADP, the decrease in the early hr. was similar to NAD, but afterwards the increase was only slight, so that by hr. 7 it did not approach the original value. A possible reason is that the nuclear adenine limitation caused by ethionine is less severe than that of the cytoplasm.

- 8458 DAILY AND HOURLY KINETICS OF TRANSFORMATION OF CHOLESTEROL-26-C¹⁴ INTO BILE ACIDS. (Fr.) Chevallier, F. (Atom. Energy Comm., Saclay, France) and C. Lutton. Bull. Soc. Chim. Biol. (Paris) 48(2):295-311, 1966.

In rats receiving a synthetic diet containing cholesterol-26 labeled with radioactive carbon, isotopic equilibrium was established on or about day 20 of feeding. Hourly determinations of the elimination of radioactive CO₂ showed that the transformation of cholesterol into bile acids was directly dependent on digestive function rather than nyctohemeral rhythms. Rats which were fed between midnight and 2 A.M. showed a virtually constant rate of CO₂ production between 7 A.M. and 6 P.M. increased the rate gradually, during the evening, to approx. twice the daytime level; increased it again, slightly, during the first hr. after feed was presented, then began a gradual decline to the stable daytime level. Rats fed between noon and 2 P.M. showed a similar pattern but with CO₂ production peaking at noon instead of midnight. However, the periods of increment and (especially) decrement were protracted. Under controlled conditions, adult rats transformed an av. of 12.5 mg of cholesterol per day into bile acids (range: 9.4-19.2 mg). At sacrifice, the levels of cholesterol-specific radioactivity found in the blood and the liver were equal, with 48% of the mobile cholesterol demonstrable in the rest of the body.

- 8459 EXCRETION OF BILE ACIDS BY THREE MEN ON A FAT-FREE DIET. (E.) Ali, S. S. (U. Karachi, Pakistan), A. Kuksis and J. M. R. Beveridge. Canad. J. Biochem. 44(6):957-969, 1966.

The total output of fecal bile acids of three middle-aged men on fat-free diets ranged from 130-650 mg/day. The separation and determination of fecal bile acids was conducted the last 4 days of three 8-day periods of a fat-free diet. Lithocholic and deoxycholic acids accounted for 65-80% of the total bile acid excretion. Other common bile acids were present, but in considerably lower quantities (0.5-11%).

BILIARY METABOLISM

the following uncommon fecal bile acids (tentative identification) each accounted for 0.5-7% of the total excretion: $3\alpha,12\beta$ -dihydroxy-, $3\beta,12\beta$ -dihydroxy-, $3\alpha,7\beta$ -dihydroxy- and 3α -monohydroxy-7-ketocholanic acids. Significant variations were found in the conc. of several of the bile acids both between different samples from the same subject and between samples from different subjects.

- 0 MODE OF ACTION OF CHOLINE. I. FATTY ACID COMPOSITION OF LIVER, SERUM, AND ADIPOSE TISSUE OF CHOLINE-DEFICIENT RATS. (E.) Chalvardjian, A. (Hosp. Sick Child., Toronto, Canada). Canad. J. Biochem. 44(6):713-724, 1966.

young male albino rats on fat-free, 4% fat or 30% fat diets which were either choline primed or deficient, no quantitative similarities in fatty acid pattern existed between hepatic triglycerides on the one hand and adipose tissue, serum triglycerides and dietary fat on the other. In fact, the fatty acid pattern of tissues, particularly the triglyceride fraction, showed more prominent changes. In comparison was made between groups on the basis of differences in the level of dietary fat than on the basis of choline supplementation or deficiency. A relative preponderance of 16-carbon fatty acids occurred in hepatic triglycerides of choline-deficient animals fed the fat-free or low-fat diet, while, when the fat was increased to 30%, the fatty acid composition bore a closer resemblance to that of dietary fat.

- 1 EFFECT OF α -TOCOPHEROL UPON LIPID PEROXIDATION AND DRUG METABOLISM IN HEPATIC MICROSOMES. (E.) Gram, T. E. and J. R. Fouts. Arch. Biochem. Biophys. 114(2):331-335, 1966.

an *in vitro* system consisting of rat liver (9,000 g) supernatant and a TPNH-generating system, significant lipid peroxidation was observed during incubation at 37° C which when plotted against the amount of supernatant gives a bell-shaped curve. Such a system using rabbit liver produces negligible peroxidation which follows a linear relationship with supernatant vol. When hexobarbital or codeine was incubated with the rat liver system, their metabolism is linear with time and reaches an early plateau (indicating enzymatic inactivation) and peroxidation is slightly stimulated. In contrast, the addition of aminopyrine, zoxazolamine, morphine or 3,4-benzpyrene markedly reduced or abolished peroxidation. This suggests that the microsomal drug-metabolizing enzymes may have a greater resistance to the denaturing effects of lipid peroxides than the enzymes involved in ascorbic acid synthesis. Homogenization of the liver in the presence of α -tocopherol abolished lipid peroxidation but did not influence the metabolism of hexobarbital or codeine. Thus it would seem that lipid peroxidation and drug-enzyme inactivation in the rat liver are coincidentally but not causally related.

- 2 HYPOGLYCAEMIA, ELEVATED LIVER GLYCOGEN AND DIMINISHED LIVER AMYLASE IN PANCREATECTOMIZED-ENTERECTOMIZED DOGS. (E.) Hiatt, N. (Cedars-Sinai Med. Res. Inst., Los Angeles, Cal.). Nature (London) 210(5034):423-424, 1966.

hypoglycemia with obliteration of the glucose tolerance curve occurred in 3 dogs subjected to delayed enterectomy (with a vagotomy) following pancreatectomy. The liver glycogen was abnormally high during this period of hypoglycemia, while the amylase levels were about one third the pre-enterectomy levels. This change from hyperglycemia (due to the pancreatectomy) to hypoglycemia developed within 7-15 days after the enterectomy despite i.v. infusion of large amounts of glucose without insulin. However, amylase infusion increased the blood glucose level and decreased the liver glycogen content. The simultaneous removal of these two organs does not produce this effect.

- 3 SITES OF PROTEIN SYNTHESIS AND MIGRATION OF PROTEINS IN RAT HEPATIC CELLS: ELECTRON MICROSCOPIC AUTORADIOGRAPHIC STUDY. (Fr.) Droz, B. (Atom. Energy Comm., C.E.N., Saclay, France). C. R. Acad. Sci. (Paris) 262(15) (Ser. D):1654-1656, 1966.

30 min. after i.v. inj. of tritiated L-leucine into rats, autoradiographic activity was demonstrable in the intracellular ergastoplasm and mitochondria of hepatic cells.

HEPATIC METABOLISM

At 5 min. after inj., it was localized in the ergastoplasmic cisternae and in vesicles leading to the Golgi apparatus; at 10 min., in Golgi vesicles and sacculi. At 20 min., intense radioactivity in the Golgi apparatus was localized in the sacculi, and especially at the ends of the sacculi, which were distended to form vacuoles. Some radioactivity was also demonstrable in vacuoles which were near Disse's spaces and in a few microbodies. In animals inj. i.p., radioactivity decreased progressively in the Golgi apparatus between 1½-6 hr. after inj., while radioactive vacuoles were dispersed increasingly through the peripheral cytoplasm and Disse's spaces, accompanied by increasing appearance of radioactive microbodies. The author concludes that proteins synthesized in hepatic cellular ergastoplasm accumulated in the Golgi apparatus prior to being discharged into the peripheral cytoplasm.

- 8464 EXPERIMENTAL HEPATIC REGENERATION IN THE RAT. II. LIGATION OF THE GASTRODUODENAL VEIN. (It.) Cavallotti, C. (U. Rome) and N. Garcea. Boll. Soc. Ital. Biol. Sper. 42(2):85-88, 1966.

Hepatic regeneration was studied in 40 Wistar rats (wt. 200 g) subjected to partial hepatectomy (65% Crandall-Drabkin technic) along with double ligation of the gastroduodenal vein at its entry into the portal vein. Animals subjected to this technique regained 50.2% of initial liver wt. by day 2, 72.6% by day 10, and 82.4% by day 12. Comparison with other experimental conditions indicates a lower percentage of hepatic regeneration (82.4%) by day 18 with the above technic as compared to partial hepatectomy alone (101.3%) or in combination with ligation of the splenic vein (94.3%). Total body wt. was also lower in animals with gastroduodenal vein ligation, and mortality was higher than in the other 2 groups. It is concluded that ligation of the gastroduodenal vein deprives the regenerating hepatic remnant of the amount of blood which normally this vein emits into the portal vein. (See also no. 8465.)

- 8465 EXPERIMENTAL HEPATIC REGENERATION IN THE RAT. III. LIGATION OF THE SUPERIOR MESENTERIC VEIN. (It.) Cavallotti, C. (U. Rome) and G. Cimaglia. Boll. Soc. Ital. Biol. Sper. 42(2):89-92, 1966.

Hepatic regeneration was studied in 40 Wistar rats (wt. 200 g) subjected to partial hepatectomy (65%; Crandall-Drabkin method) along with ligation of the superior mesenteric vein proximal to its entry into the portal vein. With this technic, mortality was 60% (16 of 40 animals). Surviving animals regained 44.2% of initial liver wt. by day 2, 65% by day 10, and 76.7% by day 18. By comparison, hepatic regeneration at day 18 reached 101.3% of initial liver wt. following hepatectomy alone, 94.3% following hepatectomy with splenic vein ligation, and 82.4% following hepatectomy with gastroduodenal vein ligation. Total body wt. at day 18 was also lowest in animals subjected to hepatectomy and superior mesenteric vein ligation. It is concluded that hepatic regeneration is significantly diminished when the hepatic blood supply to the residual stump is diminished, as in the case of ligation of the superior mesenteric vein. (See also no. 8464.)

- 8466 BIOSYNTHESIS OF TRITIATED BILIRUBIN AND STUDIES OF ITS EXCRETION IN THE RAT. (E.) Lester, R. (Boston City Hosp., Mass.) and P. D. Klein. J. Lab. Clin. Med. 67(6):1000-1012, 1966.

A procedure is described using the principle of enolization exchange in the preparation of H^3 -labeled δ -aminolevulinic acid in a radiochemically pure form and specifically labeled at positions C-3 and C-5. Following i.v. admin. of the compound (100-1,000 μ g) to Sprague-Dawley rats prepared with an external biliary fistula, H^3 -labeled bilirubin was crystallized from bile excreted during the subsequent 24 to 48 hr. Radiochemical purity was established and the stability of molecular labeling was shown *in vivo*. Comparative rates of excretion of unconjugated bilirubin, bilirubin glucuronide, mesobilirubinogen, and taurocholate were determined by the dual label technic. Unconjugated bilirubin was excreted at lower rates than each of the other 3 metabolites examined. The availability of tritiated preparations of δ -aminolevulinic acid provides the technical means to perform investigations in several areas of bile pigment physiology.

HEPATIC METABOLISM

67 THE UPTAKE OF LIPIDS BY RAT LIVER CELLS. (E.) Higgins, J. A. (U. Liverpool, England) and C. Green. Biochem. J. 99(3):631-639, 1966.

in vivo studies of hepatic parenchymal cells isolated from rats showed that 3 chylomicron components (unesterified cholesterol, cholesterol esters and triglycerides) were taken up at the same rate, confirming the binding of the chylomicron as a whole. Hydrolysis of chylomicron triglyceride bound to hepatic cells took place *in vitro* whether the initial uptake occurred *in vitro* or *in vivo*, with comparable rates and degrees of lipolysis. The *in vitro* binding, at least, did not appear to be a process of random adsorption, but obviously affected only a relatively small area of the cell surface, with approx. 200 chylomicrons being taken up per cell. "Ghost" hepatic cells showed the same binding capacity and lipolytic activity as intact cells. Triglyceride associated with hepatic cells was accessible to addition of clearing factor lipase, confirming that it had not been reformed inside the cell after lipolysis and suggesting that the cell plasma membrane was the actual site of hydrolysis. Among the subcellular fractions, plasma membrane showed the greatest capacity per unit wt. for both chylomicron and non-esterified fatty acid binding, as well as the greatest capacity for triglyceride hydrolysis. Inside the cell, non-esterified fatty acids were treated in the same way, whether they were taken up originally from the circulation as such or derived from chylomicrons. Comparison of their rate of incorporation into compound lipids (especially phospholipid) with the rate of hydrolysis of chylomicron triglycerides at the cell surface suggested that the latter was a limiting factor for the rate at which they were metabolized. Studies of the action of clearing factor lipase on endogenous hepatic cell lipids during incubation with normal versus post-heparin plasma, like studies of its effects on hydrolysis of bound chylomicrons under these conditions, argued strongly against the possibility that chylomicron hydrolysis took place intracellularly, within pinocytotic vessels (formed of plasma membrane) which were pinched off upon contact with the chylomicrons.

68 THE EFFECT OF CORTICOSTEROIDS AND ALTERED ADRENAL FUNCTION ON LIVER REGENERATION FOLLOWING CHEMICAL NECROSIS AND PARTIAL HEPATECTOMY. (E.) Davis, J. C. (U. Liverpool, England) and T. A. Hyde. Cancer Res. 26(2)(Pt. 1):217-220, 1966.

The inhibitory effect of various corticosteroids on the mitotic rate of the proliferating liver was studied in adult albino male mice following CCl_4 (0.2 ml s.c.)-induced centrilobular hepatic necrosis or partial hepatectomy. When initial liver damage was caused by CCl_4 , cortisol (0.1-12.5 mg s.c.) produced a linear dose-response. In partially hepatectomized animals, cortisol (1-5 mg s.c.), corticosterone (1 mg in propylene glycol), and ACTH (0.05 I.U.) all produced a significant fall in the mitotic counts. Inj. of propylene glycol by itself caused marked depression as compared with the uninjected or saline controls. Various unspecific procedures, such as starvation or slightly painful inj., also lowered the mitotic rate; this effect was abolished by adrenalectomy. The higher mitotic rate in mice inj. with carbon tetrachloride as compared with the partially hepatectomized animals may be due to the greater anorexia produced by the operation than the injection.

69 CELL POPULATION DYNAMICS IN THE LIVER. A REVIEW OF QUANTITATIVE MORPHOLOGICAL TECHNIQUES APPLIED TO THE STUDY OF PHYSIOLOGICAL AND PATHOLOGICAL GROWTH. (E.)(Rev.) Steiner, J. W. (U. Toronto, Canada), Z. M. Perz and L. B. Taichman. Exp. Molec. Path. 5(2):146-181, 1966.

In this survey of the literature on the quantitative morphological assessment of the growth of normal and pathological cells of the liver, the theoretical aspects of population dynamics are discussed in relation to the use of conventional histological sections, DNA labeling, and other methods. Types of physiological growth (initial and renewal) in the undamaged liver, as well as reparative and pathological growth following partial hepatectomy, biliary obstruction, chronic dietary injury, the admin. of necrotizing or carcinogenic agents, are reviewed. Various meaningful principles are deduced from the data examined.

HEPATIC METABOLISM

- 8470 THE EFFECT OF DILANTIN SODIUM ON LIVER DNA AND RESTITUTION. A PRELIMINARY REPORT. (E.) Shafer, W. G. (Indiana U. Sch. Dent., Indianapolis). J. Oral Ther. Pharm. 2(5):319-323, 1966.

Liver cell nucleic acid synthesis and proliferation is stimulated in mice and rats which have been treated with 5,5-diphenylhydantoin (I) which indicates that I is apparently not connective tissue- or fibroblast-specific. In livers from male Swiss albino mice which had received 13.5 mg of I over 14 days prior to inj. with 12 μ c of tritiated thymidine there were 6 times as many thymidine-labeled cells as in the control livers. The nuclear grain count of these treated animals was too numerous to be counted, whereas the count in the controls was between 6-10. When a hepatectomy followed I treatment, it was seen that I stimulated liver restitution.

- 8471 LIVER REGENERATION IN STARVED RATS. (E.) Doljanski, F. (Hebrew U. Sch. Med., Jerusalem, Israel), J. Rosenthal and S. Eisenberg. Exp. Molec. Path. 5(3):263-272, 1966.

No retardation in liver regeneration occurred in adult, male rats which had been starved both 24 hr. prior to a partial hepatectomy and 48 or 72 hr. postoperative before the liver was examined. The restoration with respect to liver wt. was 52.7% in fed animals and 60.4% in the starved ones, 48 hr. after the operation. The figures were 70% and 73%, resp., 72 hr. after the operation. However, the protein/DNA ratio was considerably increased in the starved groups 48 and 72 hr. after partial hepatectomy, whereas in the fed group it was practically normal by 72 hr. A study on the electrophoretic mobility of isolated single liver cells showed a 20-30% increase in the mobility of liver cells 48 hr. after partial hepatectomy in both the starved and fed groups.

- 8472 TIME COURSE DIFFERENCES IN THE METABOLISM OF DRUGS BY HEPATIC MICROSOMES FROM RATS, RABBITS AND MICE. (E.) Gram, T. E. (Iowa State U. Coll. Med., Iowa City) and J. R. Fouts. J. Pharmacol. Exp. Ther. 152(3):363-371, 1966.

Time course studies on the metabolism in hepatic microsomes from rabbits, rats and mice were conducted using hexobarbital, codeine, zoxazolamine, p-nitrobenzoic acid Neoprontosil, aminopyrine and benzpyrene. Relatively early deviation from linear metabolism (sometimes less than 15 min.) was observed with rat liver microsomes, whereas rabbit and mouse liver microsomes metabolized drugs linearly with time for much longer periods (60-90 min. in some cases). The early departure from linearity seen with rat liver microsomes was not influenced by doubling the substrate conc., doubling the cofactor conc. or addition of excess reduced nicotinamide adenine dinucleotide phosphate. Rabbit liver microsomes were barely affected by a 60-min. preincubation or by an incubation in hypotonic media, whereas rat liver microsomal activity was markedly reduced by such treatment.

- 8473 POTENTIAL AND RESISTANCE MEASUREMENTS OF RAT LIVER CELLS IN SITU. (E.) Schanne, O. (U. So. California, Los Angeles) and E. Coraboeuf. Nature (London) 210(5043):1390-1391, 1966.

In situ measurements of the liver with intracellular microelectrodes (filled with 3M KCl) showed an av. membrane potential of 50.69 ± 1.33 mV. Thirty min. after clamping the trachea of these same rats, this liver membrane potential had dropped to half its original value. The membrane potential of a muscle, which was recorded simultaneously, stayed constant over the same period, indicating a difference in the membrane properties of these two cells. Using double-barrelled microelectrodes a value of 37 ohm cm^2 was obtained as a mean of the membrane resistance of the rat liver cell. Alteration in ionic conc. of the bathing soln. (with simultaneous measurement of the membrane potential) revealed a high Na permeability.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

- 8516 SEARCH FOR A SIMPLE METHOD FOR EVALUATING THE EFFICACY OF ANTIDIARRHEAL MEDICATIONS. (REPORT ON 5-CHLORO-8-ACETOXYQUINOLINE.) (Fr.) Wyss, J. (City Hosp., Yverdon, Switzerland). *Ther. Umsch.* 23(4):151-157, 1966.

When 5-chloro-8-acetoxyquinoline (Silitol) was admin. to diarrhetic patients suff. from acute gastroenteritis (44 cases), shigellosis (12) and colitis following an infection (3), normal defecation rhythms (i.e., return to 1 stool per day or what ever other pattern had preceded the illness) were reestablished in all cases with 10 days or less, accompanied by disappearance of all other symptoms. A similar r. was obtained in 8 of 12 patients with intestinal amebiasis, the remaining 4 resp. when treatment was continued somewhat longer. Among 3 groups of diarrhetic patier suffering from acute colitis secondary to amebic infection (16), chronic non-spec colitis (13) and acute enterocolitis (5), prompt control of diarrhea and disappea of all other symptoms was achieved by 9, 4, and 3 patients, resp.; moderately goo results by 5, 4 and 2, resp; no results by 2, 5 and 1, resp. An additional patier suffering from intestinal tuberculosis, failed to respond. There were no signific differences between patient groups, as concerned optimal dosage and initial respo was usually seen by the third day of treatment.

- 8517 DETERMINATION OF SERUM PEPSINOGEN IN THE COURSE OF VARIOUS GASTROINTEST. DISORDERS. CLINICAL AND PHYSIOPATHOLOGICAL IMPLICATIONS OF THE LEVEL DE STRATED. (Fr.) Chariot, J. (Bichat Hosp., Paris), J. P. Hardouin, J. Lanfranchi, P. Housset and C. Debray. *Sem. Hop. Paris* 42(24):1491-1502, 1966.

Mean fasting levels of serum pepsinogen activity (expressed as clinical units: i. as μg tyrosine/ml serum liberated over 24 hr. at 37°C) were determined for a cont group and for several groups of patients with gastrointestinal disorders. (Also studied were patients with hepatic cirrhosis and 5 groups of patients who had unde gone total or partial gastrectomy.) In two patients with Zollinger-Ellison syndro who had not yet undergone surgery, serum pepsinogen activity was recorded as 750 a 820 clinical units, resp; in two who had undergone subtotal (2/3) gastrectomy, it 324 and 805, resp. Comparable (mean) tabulations for controls and for patients wi gastric ulcer, duodenal ulcer, gastric cancer and hypertrophic gastritis were 192, 402, 250 and 673 clinical units, resp. No activity was demonstrable after total g trectomy. The degree of activity after partial gastrectomy depended on the (infla tory) condition of the gastric stump and the location of the anastomotic opening. Mean values for patients with hepatic cirrhosis did nor differ significantly from those for controls. Serum pepsinogen activity was extremely low in atrophic gastr (57 clinical units) and activity levels below 100 units were believed to be diagno cally suggestive of this disorder. In the absence of Zollinger-Ellison syndrome, activity above levels of 600 units was considered diagnostically suggestive of the presence of giant-fold gastropathy (hypertrophic gastritis).

- 8518 THE ALDON INTESTINAL DEFLATION TUBE. (E.) Notley, R. G. (St. Luke's Hos Surrey, England). *Lancet* 2(7454):91, 1966.

The design and use of a device for decompressing distended intestine during surgery is described. Constructed of soft, flexible, non-toxic polyvinylchloride tubing, it consists of a decompression tube (with perforated walls) 14 inches long and 1/2 inch in diameter and a suction tube (connected directly to a suction apparatus) 37 inches long and 1/4 inch in diameter. The decompression tube is placed in the bowe through an incision in the center of a purse-string suture and manipulated along th distended coils in either direction; two perforations at the proximal end, occluded with the fingers during use, can be released to provide momentary increase in pressure should intestinal mucosa be caught in the wall perforations.

- 8519 VISCERAL LYMPHOGRAPHY: AN EXPERIMENTAL STUDY. (E.) Herman, P. G. (Stat U. New York, Brooklyn), D. L. Benninghoff, R. Takashima and H. Z. Mellins. *Radiology* 87(1):7-11, 1966.

A method of radiologic examination of the lymphatic structures originating from abd inal viscera is described. Under Pentothal anesthesia and endotracheal intubation, laparotomy was performed on 30 normal mongrel dogs. After identification of the

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

lymphatics by subserosal inj. of 0.2 ml of 4% Direct Sky Blue dye, cannulation was performed with a 25 to 30 gauge needle fitted to PE 50 tubing and 1 to 4 ml of contrast medium (Ethiodol, Thorotrast) was inj. by an automatic injector over a period of 20 to 60 min. Serial radiographs of the abdomen in the anteroposterior and left posterior oblique projections were obtained, and good visualization of the vessels and nodes was achieved. The organization of the lymphatic structures on the lymphograms was specific and reproducible, correlating closely with the anatomic dissections of Baum. Twenty-six dogs were sacrificed after lymphography. No significant untoward clinical, gross pathological, or histological effects were observed in 4 dogs which were subjected to a second operation (2 wk. after the lymphography) or removal of the inj. organs and first echelon lymph nodes.

- 520 BEHAVIOR OF FLUIDS AND ELECTROLYTES IN THE SMALL AND LARGE INTESTINE IN RESPONSE TO THE INFLUENCE OF LAXATIVES. A CONTRIBUTION TO THE CLARIFICATION OF THEIR MECHANISM OF ACTION. (Ger.) Forth, W. (U. Saarland, Homburg, Germany), W. Rummel, J. Baldauf, H. Andres and H. Wilbert. Naunyn Schmiedeberg. Arch. Exp. Path. 254(1):18-32, 1966.

The effects of 6 laxatives were tested in rats bearing closed jejunal or colonic loops (the latter comprised of the entire large intestine from the cecal junction to the rectum) filled with Tyrode solution 1 hr. prior to sacrifice. In low conc., bisacodyl completely inhibited calcium resorption and resorption of fluid through the colonic wall. Sodium resorption in the colon was reduced by approx. 50% while the movement of potassium into the colonic lumen was more than doubled. At these dose levels, jejunal resorption remained unaffected, although glucose transport in the jejunum was diminished at higher dose levels. Both 4,4'-dihydroxyphenyl-(2-pyridyl)-methane and 4,4'-diacetoxydiphenyl-(2-pyridyl-6-methyl)-methane had similar effects to those of bisacodyl, as did dihydroxydiphenylisatin. Neither diacetoxydiphenylisatin nor an aqueous soln. of phenolphthalein had any discernible effect at the dose levels tested. It is concluded that the agents which were active inhibited the so-called sodium pump (thus inhibiting resorption of fluid) with simultaneous stimulation of the movement of fluids into the intestinal lumen.

- 521 INTESTINAL MUCOSA BIOPSY IN INFANTS AND CHILDREN USING THE CROSBY-KUGLER CAPSULE. (It.) Mastella, G. (Alessandri Child. Hosp., Verona, Italy) and S. Meli. Fracastoro 59(1):1-38, 1966.

Intestinal mucosa biopsy specimens were obtained using the Crosby-Kugler capsule in 30 infants and children (age 5 mo.-10 yr.), of whom 5 were normal, 8 had cystic fibrosis, and 17 had chronic diarrhea of varying etiology. Eighteen patients were less than 1 yr. old and 5 weighed less than 6 kg. The mucosa of the duodenum and jejunum was normal in 2 of 3 patients with gluten intolerance after 2.5 mo. of diet; the other patient showed partial atrophy. Of 3 patients with malnutrition and lactose intolerance, 2 showed subnormal mucosa and 1 total atrophy. Of 2 patients with malabsorption due to intolerance to cow's milk, 1 had partial and 1 total mucosal atrophy. A patient with probable pancreatitis showed almost total atrophy. Two patients with severe malnutrition and chronic diarrhea had marked atrophy of the duodenal mucosa. Of 6 patients with chronic diarrhea of unknown etiology, 1 had normal mucosa while the others showed changes ranging from partial to total atrophy. Among 8 patients with cystic fibrosis, 2 had normal mucosa, 1 had marked cellular infiltration and alterations of the villi, 4 showed an abundance of dense and fibrous mucus, and 1 (with malabsorption) had marked atrophy. The significance of these histological findings is discussed.

- 522 A NEW IMPREGNATION DEVICE FOR LOCATING THE SITE OF GASTROINTESTINAL TRACT BLEEDING. (E.) Bray, R. S. Rhode Island Med. J. 49(5):289-293 & 302, 1966.

The author describes a new device (impregnation core) for use in the string impregnation test to facilitate the localization of gastrointestinal bleeding. The core was used as an office procedure in 37 patients; results were positive in all 7 duodenal ulcer patients with a niche and in 6 of 9 with a deformity only, in 1 of 3 with gastric ulcer, in 7 of 11 with sliding hiatus hernia, in 1 patient with esophageal varices, in 3 with gastric ulcer, and in 2 of 3 with prolapsing antral

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

folds. Disadvantages of the method include difficulty in rapid swallowing of the soft-textured string, use of a time-consuming and awkward mercury-containing finger cot, and inability to visualize clearly the progress of the tape and cross markers during fluoroscopy. The importance of the slow bleeder is stressed, and a new method for the study of hematemesis is discussed.

- 8523 STAPHYLOCOCCAL ENTEROCOLITIS - TREATMENT WITH ORAL VANCOMYCIN. (E.) Khan, M. Y. (VA Hosp., Minneapolis, Minn.) and W. H. Hall. Ann. Int. Med. 65(1):1-8, 1966.
Vancomycin (p.o. 0.5 g every 4-6 hr., for 3-5 days) proved highly effective, simple to use and nontoxic in the treatment of 62 cases of staphylococcal enterocolitis. Over the past decade, 109 cases were observed in this hospital whose ages averaged 63 yr. and all of whom were receiving various antibiotics, either as an adjunct for surgery (77 cases) or for medical conditions, when staphylococcal enterocolitis developed. The diagnosis was made by the presence of diarrhea and a positive smear of culture of the stool. The diarrhea began 3-9 days after the start of the antibiotics. Sensitivity of the staphylococci to vancomycin was tested in 57 patients and no strain was found resistant, whereas there was a notable resistance of the organisms to the more commonly used antibiotics such as neomycin and kanamycin.

GASTROINTESTINAL DISEASES

GENERAL

8546

HISTOLOGICAL AND ANIMAL EXPERIMENTAL STUDIES ON THE PROPHYLAXIS OF ABDOMINAL ADHESIONS WITH TRASYLOL. (Ger.) Grundmann, E. (Farbenfabriken Bayer AG., Wuppertal-Elberfeld, Germany). Bruns Beitr. Klin. Chir. 212(336-350, 1966.

Extensive adhesions which can be produced by inj. 1.0 g talcum powder (i.p.) were prevented when 600,000 U (200,000 kallikrein inhibitory units/ml) of Trasylol were also inj. shortly before closing the abdominal wall of rabbits. Control rabbits received 3.0 ml of the Trasylol solvent. In experiments with Wistar rats groups of 10 rats each were opened and adhesions produced by electrocauterization. Immediate before closure, then daily for 9 more days (with a 2-day pause between days 4 and 5 the groups received resp. i.p. inj. of: 1.0 ml saline (controls); 1.0 ml Cialit soln. (controls); Trasylol, 10,000 U; Trasylol, 50,000 U; soybean trypsin inhibitor 1.0 mg/kg; Macrodex 6%, 2.0 ml; Periston-N 2.0 ml; AMCHA (aminomethyl-cyclohexane carbonic acid, an antifibrin) 400 mg/kg; heparin 10 mg/kg; prednisone 2.0 mg/kg; deoxycorticosterone, 2.0 mg/kg; and chondroitin-sulfate 400 mg/kg. On day 14 the animals were sacrificed and the extent of adhesions expressed in adhesion surface in cm². The 1.91-1.93 cm² adhesions of the two control groups were reduced by Trasylol to 0.06 and 0.05 cm², resp.; to 0.84, 0.71, and 0.61 by the soybean inhibitor and the two high molecular weight dextrans, resp.; to 1.12 and 1.20 cm², resp., by the two antifibrins; to 1.06 cm² by prednisone; 1.22 by 1; and 1.74 cm² by the mucopolysaccharide. Only Trasylol, and to some extent the soybean inhibitor and the two dextrans, had an effect. The effect of prednisone was at the limit of statistical significance ($P = 0.04$). Histologic studies performed on 2 x 20 additional rats (Cialit controls and 10,000 U Trasylol) sacrificed at 2, 10, 20 and 60 min., then 2, 4, 8 and 24 hr., and 2 and 4 days after surgery showed that Trasylol acts by inhibiting the inflammatory process initiated by electrocauterization by decreasing damage to the serosa, and decreasing subsequent granulocytic infiltration. Fibrin production does not seem to be influenced however, which makes the author speculate on the possibility that simple serosa defects (without damage to the muscularis) may heal without adhesions, and that peritoneal fibrinolytic activity plus the effect of histiocytes and macrophages are enough to bring this about, provided that an inflammatory process can be prevented from initiating.

8547

THE RELATIONSHIP BETWEEN ARTERIOSCLEROSIS AND CARCINOMA. (Ger.) Zschoch, H. (Karl-Marx-U., Leipzig, Germany). Virchow Arch. Path. Anat. 341(2): 102-107, 1966.

The rate of incidence of severe, generalized arteriosclerosis among 5,052 autopsied patients with bronchogenic, cervical, gastric or cholecystic carcinomas (all 4 sites combined) was 47.1%; among 14,801 without carcinomas, it was 57.7%. The rate of incidence of severe coronary sclerosis among the carcinomatous patients included in the study was 30.0%; among the non-cancerous patients, it was 36.4%. It is concluded that a negative statistical correlation existed between both sclerotic disorders and the malignancy. The rate of incidence of severe, generalized arteriosclerosis among subgroups of patients with and without bronchogenic carcinoma was 49.5 and 52.7%, resp.; among those with and without cervical carcinoma, it was 21.5 and 46.6%, resp.; among those with and without gastric carcinoma, it was 52.8 and 52.5%, resp.; among those with and without cholecystic carcinoma, it was 51.0 and 52.6%, resp. It is concluded that a negative statistical correlation existed between severe, generalized arteriosclerosis and both bronchogenic and cervical (but not gastric and cholecystic) carcinomas.

EXPERIMENTAL CHOLERA. A CANINE MODEL. (E.) Sack, R. B. (Johns Hopkins U. Sch. Med., Baltimore, Md.), C. C. J. Carpenter, R. W. Steenburg and N. F. Pierce. Lancet 1(7456):206-207, 1966.

A cholera syndrome, resembling human cholera, has been experimentally produced in approximately 35% of mongrel dogs challenged orally with 3 strains of Vibrio cholerae. An adequate fasting period, followed by alkalinization of the stomach, and the admin. of large numbers of vibrios in the logarithmic phase of growth are probably important predisposing factors. In a group of re-challenged dogs, the infection rate was the same as in dogs challenged for the first time, suggesting that no immunity had been produced. The canine model indicates that in cholera most of the fluid and electrolyte loss originates in the jejunum and ileum. The model can be

ed to evaluate the effects of various vibrio toxins and the possibility of anti-toxic immunity.

- 49 EXPERIMENTAL AMYLOIDOSIS. ROLE OF ANTIGENICITY AND RAPID INDUCTION. (E.) Janigan, D. T. (U. Kansas Med. Ctr., Kansas City) and R. L. Druet. Am. J. Path. 48(6):1013-1025, 1966.

The role of antigenicity and rapid induction was investigated in male C57BL/10J mice during protein-induced experimental amyloidosis of the liver and spleen. Regardless of the method of induction, all amyloid exhibited identical histological and staining features. Mice were given daily inj. of 0.3 ml quantities 7 days a wk., except for gelatin and casein hydrolysate which were given 5 days a wk.; in the increased inj. group, daily inj. of azocasein in 0.6-1.0 ml quantities were admin. in 2 divided doses. Comparative studies on the amyloidogenic properties of various soluble proteins showed that increased antigenicity was a sufficient condition to convert (1) non-amyloidogenic protein (gelatin) into an amyloidogenic protein (azogelatin); (2) a weak amyloidogenic protein (bovine serum albumin) into a strong amyloidogenic protein (azoalbumin); and (3) a strong amyloidogenic protein (casein) into an even more potent amyloidogenic protein (azo-casein). Conversely, loss of antigenicity through loss of molecular size contributed an adequate condition to convert amyloidogenic proteins (casein and azo-casein) into non-amyloidogenic materials (casein and azocasein hydrolysates). Throughout the study, progressive increases in antigenicity were associated with progressive decreases in amyloid induction times which could be ranked in the following decreasing order: azogelatin (28-32 days) > casein (22 days) > azoalbumin (20 days) > azo-casein (10 days) > and with large amounts of azo-casein (6-8 days).

- 50 THE BEHAVIOR OF CHLORINE IN THE SWEAT OF CHILDREN WITH RECURRENT PAROTITIS AND SUBMAXILLARITIS. (Pol.) Burczynski, E. (Acad. Med., Warsaw, Poland), W. Leskiewicz and I. Krupinska-Sanecka. Otolaryng. Pol. 19(1):97-101, 1966.

A total of 22 children with recurrent parotitis and 2 with submaxillaritis were studied with reference to the chlorine content in sweat. An increased level of chlorine (56 - 88 mEq/liter) was found in 4/24. Additional studies demonstrated abnormal levels of pancreatic enzymes in duodenal contents, and excessive amounts of neutral fats in feces. In 20 of 24, normal chlorine values in sweat and no evidence of pancreatic malfunction were found. The 4 cases were diagnosed as an abortive form of mucoviscidosis (=panexocrinopathic syndrome). Panexocrinopathy occurs at a frequency of 1/2,000 births in the province of Gdansk (Poland), whereas in America, it occurs at a frequency of 1/600 births (according to Shwachman and Kulczycki).

- 51 THE EMERGENCY ABDOMINAL ANEURYSM. (E.) Coles, J. C. (U. Western Ontario, London, Canada), J. Buttiglierio and G. Fischer. Arch. Surg. (Chicago) 93(1):6-9, 1966.

Improved survival rate in resection of emergency abdominal aneurysms was demonstrated by 102 resections and graft replacements with rupture being the factor precipitating the emergency in 74 of the cases. The etiology in all but 3 patients was atherosclerosis, while 70% of the patients had associated hypertension or heart disease or both. The total survival in the 10-year period under study is 65% with a rate for the last 3 years being 80%. This is attributable to a bold operative approach and appreciation that a near poikilothermic patient can be rendered hypothermic by massive transfusion of cold blood. Uremia, shock, and pulmonary complications were each the cause of approx. one-third of the deaths. The use of mannitol together with a more aggressive treatment of shock helped to reduce uremia deaths in the last 3 years. The number of complications is high but two-thirds of the patients operated were returned to previous status.

- 52 STEROID THERAPY AND STRONGYLOIDIASIS. (E.) Willis, A. J. P. (U. Ibadan Coll. Hosp., Nigeria) and C. Nwokolo. Lancet 1(7452):1396-1398, 1966.

Two young male patients with nephrotic syndrome developed steatorrhea due to strongyloides stercoralis after steroid treatment (prednisone, 20-40 mg daily for varying periods of time up to 6 mo.). Both had multiple courses of steroids and

GENERAL

were under observation for long periods of time without evidence of gastrointestinal disturbance. The first of 3 attacks of diarrhea occurred 1 yr. after initiation of steroid therapy and 6 mo. after the drug had been stopped in one patient; the other had his first known episode of strongyloidiasis during course 4 of steroid treatment, 4 yr. after he was first seen. In both patients, large numbers of larvae were seen in the jejunal aspirate and in the stool, and jejunal biopsy showed mucosal damage. In each instance the infection responded to treatment (chloramphenicol, dithiazine, thiabendazole, or sulfadimidine), but was not eradicated. The complication has not been observed among large numbers of patients with nephrotic syndrome not treated with steroids. It is suggested that steroid therapy upsets the host-parasite relationship, possibly by depressing antibodies, thereby allowing the parasite to become more invasive.

- 8553 MESENTERIC ARTERIAL INSUFFICIENCY FOLLOWING ABDOMINAL AORTIC RESECTION. (E.) Gonzalez, L. L. (U. Cincinnati Coll. Med., Ohio) and M. S. Jaffe. Arch. Surg. (Chicago) 93(1):10-20, 1966.

The clinical findings in three patients who had had abdominal aortic resection with division of the inferior mesenteric artery and replacement by prosthetic graft prior to the symptoms of mesenteric artery insufficiency are presented. The symptoms in all three were relieved by revascularization of mesenteric circulation using a bypass graft from the earlier placed aortic graft. In all cases the superior mesenteric artery was occluded and the large meandering mesenteric collateral artery could not develop due to the earlier division of its source, thought to be the left colic branch of the inferior mesenteric artery. In two patients a prosthetic graft was anastomosed directly to the superior mesenteric artery distal to the occlusion; whereas, in the other patient a segment of the saphenous vein was anastomosed to a dilated meandering mesenteric artery. The apparent advantages of this latter approach warrant its continued use.

- 8554 EXPERIMENTAL CHOLERA. MORPHOLOGIC EVIDENCE OF CYTOTOXICITY. (E.) Goldstein, H. B. (Walter Reed Army Inst. Res., Washington, D. C.), T. G. Merrill and H. Sprinz. Arch. Path. (Chicago) 82(1):54-59, 1966.

Sixty-eight adult Walter Reed guinea pigs which had been starved for 96 hr. were fed approx. 10^8 vibrios of an 18-hr.-old culture of *Vibrio cholerae* suspended in brain-heart infusion. An additional 72 virulence control animals revealed up to 85% mortality within 72 hr. of the cholera feeding. Complete autopsies done on experimental animals sacrificed at 8, 12, 18, 24, and 72 hr. revealed acute enteritis with degenerative lesions of the endothelial cells of the lamina propria. The endothelial degeneration, visible only through electron microscopy, exists prior to any significant changes in the epithelial cells and is severe at 8 hr. In addition, focal cardiac (78%), hepatic (62%), and pancreatic (45%) lesions were found; a striking increase in Anitschkow myocytes occurred in cardiac tissue. These tissue changes suggest to the authors that a systemic toxic effect occurs in acute cholera infection.

- 8555 AMBILHAR IN AMOEBIC DYSENTERY AND AMOEBIC LIVER ABSCESS. (E.) Powell, S. J. (U. Natal, Durban, South Africa), I. MacLeod, A. J. Wilmot and R. Elsdon-Dew. Lancet 2(7453):20-22, 1966.

Ambilhar (CIBA 32,644-Ba) was admin. p.o. 2 or 3 times daily in 500 mg doses for 10 days to 100 adult African men with acute amebic dysentery (50) or liver abscess (50). Twenty-five of those with liver abscess also received i.m. dehydroemetine. (1.5 mg/kg daily) for 10 days. Of patients with acute dysentery, ulcers were healed and amebae were no longer found in 40 (80%) by day 27; in 5, ulcers were present, although amebae had disappeared; the remaining 5 (10%) were considered failures. Of 31 patients followed 1 mo. after discharge, 28 were cured, including 3 who had ulcers at the time of discharge. All patients with liver abscesses were cured after 24-38 days of treatment with ambilhar alone; 6 mo. later, 2 had recurrences which responded to subsequent dehydroemetine and chloroquine. Of patients with liver abscesses treated with ambilhar and dehydroemetine, 24 were cured after 21-33 days and remained well; 1 was considered a failure. Electrocardiographic changes, such as flattening or inversion of T waves, were frequent, but serious

radiotoxicity was not observed. Confusional mental states occurred in 4 patients. Although results indicate results superior to emetine preparations in amebic dysentery and rivaling these drugs in amebic liver abscesses, it is recommended that emetine be reserved for treatment when established forms of treatment have failed until further toxicity studies are undertaken.

- 56 THE ACUTE TOXICITY OF BARIUM SULFATE ADMINISTERED INTRAGASTRICALLY. (E.) Boyd, E. M. (Queen's U., Kingston, Ontario, Canada) and M. Abel. Canad. Med. Assn. J. 94(16):849-853, 1966.

The intragastric admin. of barium sulfate to young male CBL-Wistar albino rats (wt. 100-160 g) failed to produce death until the dose admin. reached 20-40% of body wt. These doses provoked stomach rupture followed by death in 4-28 hr. or bowel obstruction with death in 28-52 hr. Gastrointestinal bleeding and extensive arteriovenous thrombosis of body organs were observed in both instances. The thrombosis is apparently responsible for other toxic reactions in many organs. The immediate cause of death was hypothermic respiratory failure. The LD₅₀ producing death by bowel obstruction was 364 g/kg. Results suggest that barium sulfate used as a diagnostic radiopaque agent could probably not be taken in a single dose sufficiently great to produce signs of acute toxicity.

- 57 THE ROLE OF HISTAMINE IN ACUTE EXPERIMENTAL ASCARIASIS. (E.) Borella, L. E. (U. Connecticut, Storrs), J. G. Adams and M. H. Malone. J. Parasit. 52(2):295-302, 1966.

Swine pigs of both sexes (250-550 g), some infected with larvae of *Ascaris suum*, others uninfected, were exposed to histamine aerosol or injected intracardially with histamine. Spectrofluorometric analysis of tissue levels of histamine was made. Increases of blood and tissue histamine were not observed in infected animals. Significant decreases in histamine content of brain and lung tissue were found in day infected animals as compared to controls. Infected animals were more resistant to the toxic effects of histamine admin. intracardially and by aerosol. There was a positive correlation between degree of infection and degree of tolerance to histamine. Diamine oxidase-like activity of liver seemed enhanced in infected animals; however, admin. of aminoguanidine-isoniazid did not cause loss of resistance to histamine.

- 58 SERUM PROTEIN CHANGES BY PAPER ELECTROPHORESIS IN RABBIT AND HUMAN CHOLERA. (E.) Panse, M. V. (Haffkine Inst., Parel, Bombay, India) and A. N. Dohadwalla. Indian J. Path. Bact. 8(2):138-144, 1965.

Results of comparative electrophoretic studies of serum proteins from human subjects and from rabbits with and without cholera are presented. Blood was collected from patients in acute stages of the disease; all cases were bacteriologically positive with marked anuria and high specific gravity of blood. Blood was obtained by cardiac puncture from 10-day-old rabbits, 20-24 hr. after inoculation with a rabbit-passaged strain of *Vibrio cholerae*. Blood was also obtained from normal controls. There were about 15 blood samples tested in each of the four groups. Paper electrophoresis was carried out on the serums by standard procedure. Each protein fraction was eluted and its percentage of the total protein determined; a group average for each fraction was obtained. There was no marked difference in albumin conc. between normal and diseased human serums. Rabbit cholera serums showed 5% less albumin. Slight decreases of alpha-1 globulin fraction occurred in both human and rabbit with cholera, whereas alpha-2 and gamma fractions showed increase in both. Beta-globulin decreased in human and increased in rabbit cholera.

- 59 PERIODIC PERITONITIS: ANALYSIS OF 19 CASES. (E.) Munzer, D. (Damascus Hosp., Syria). Dis. Colon Rectum 9(3):168-172, 1966.

From 1955-63, 19 patients (13 male and 6 female; most between 21-40 yr. old) with periodic peritonitis were analyzed. The disease seems to have a predilection for Arabs (14), Armenians (4), and Hebrews (1). Laboratory findings showed WBC of 10,000-18,000; eosinophils 1%-6%; sedimentation rate during attacks 70-120; between attacks 10-40; fecal parasites (13 patients); fecal amebic cysts (12); albuminuria (11); pyuria (7); bilirubinuria (4); all other tests were negative. Abdominal X-rays

during attack were negative in 2 and showed retention of gas in 8; between attacks, they were negative in 5 and showed gas retention in 5; upper gastrointestinal series were negative in 3 and showed gastritis in 15; gallbladder X-rays showed good function in 16 and poor function in 1; small intestine radiology was normal in 6; barium enema of the colon was negative in 2 and showed spastic or mucous colitis in 12 and 5, resp. The first attack of periodic peritonitis is often diagnosed as appendicitis, cholecystitis, or some other acute condition requiring surgery. In most cases, laparotomy reveals nothing abnormal. In the present series, 17 patients were subjected to 1-4 operations. Nine patients complained of more than 1 attack per yr.; 4 had 1 every 3 mo.; 2 had 1 every mo.; 2 every few yr.; 2 once a yr. Predisposing factors, pathological changes, and therapy are discussed.

- 8560 FREE FATTY ACIDS FLUX THROUGH PLASMA IN PROTEIN MALNUTRITION OF INFANTS. (E.) Lewis, B. (U. Cape Town, South Africa), W. Wittmann, L. H. Krut, J. D. L. Hansen and J. F. Brock. Clin. Sci. 30(3):371-375, 1966.

The flux of free fatty acids through plasma was determined by an isotope dilution procedure using C^{14} -labelled potassium palmitate complexed with human serum albumin in 4 patients with kwashiorkor (2 male and 2 female; age 1 yr. 4 mo. to 2 yr. 4 mo. 2 with marasmus (both male; age 1 yr.-1 yr. 5 mo.), and 4 controls (all females; age 1½ yr.-3 yr. 8 mo.). Upon admission, mean fatty acid flux rate for infants with kwashiorkor and marasmus was 64.3 and 26.6 μ Eq/min./kg body wt., resp., as compared to 6.6 μ Eq/min./kg body wt. in controls. After treatment for 6-10 days, the duration depending on the initial severity of the disease and on clinical improvement, the free fatty acid flux rate in kwashiorkor patients dropped to a mean of 10.6 μ Eq/min/kg body wt. Taking the molecular wt. of serum albumin as 69,000, the molar ratio of free fatty acids to albumin in controls was 0.36-0.73 as compared to 2.6-5 in kwashiorkor patients and 3.1 in 1 patient with marasmus. Results are discussed with respect to calorie intake and to hypoalbuminemia.

- 8561 NEW THERAPY OF BILHARZIASIS AND AMEBIASIS. CLOSING REMARKS. (E.) Da Cruz Ferreira, F. S. Acta Trop. (Basel) (Suppl. 9):307-312, 1966.

The publication consists mainly of 35 papers presented at a symposium held in Lisbon from June 2 to 4, 1965 on the chemistry, metabolism, enzyme activity, immunology, mechanism of action, therapeutic effects in schistosomiasis and amebiasis, and side effects of 1-(5-nitro-2-thiazolyl)-2-imidazolidinone (CIBA 32644-Ba). In his closing remarks, Dr. Da Cruz Ferreira stresses various features of this new drug which make it superior to other drugs of similar therapeutic effect, namely its efficacy as a complete parasitological cure in schistosomiasis, its extra-intestinal amebicidal effects, its good tolerability at active dose levels, and its superior therapeutic margin. It is active against all species of Schistosoma, and its activity is not influenced by the duration or severity of the infection, nor by the age, race, or sex of the patients. Besides minor side effects, symptoms of genuine intolerance usually consist of painful epigastric cramps, severe headaches, anorexia, and vomiting. Other side effects of special attention include frequent ECG changes, mainly involving the T wave neuropsychic effects ranging from severe headaches to convulsive attacks with infrequent hallucinations, and transitory impairment of spermatogenesis. Several dosage schedules are described. Continued trials and evaluations are strongly recommended.

- 8562 A STUDY ON IMMUNOGENIC AND ANTIGENIC ACTIVITY OF WHALE OIL AND HEAT-INACTIVATED DYSENTERY VACCINE IN COMBINATION WITH PRODIGIOSAN. (Rus.) Gorbunova E. S. (Vladivostok Med. Inst., U.S.S.R.). Antibiotiki 11(2):154-157, 1966.
- The admin. of prodigiosan (a new polysaccharide antibiotic isolated from B. prodigiosus) in conjunction with 2 anti-dysentery vaccines, one prepared from bacterial factors from whale oil and one by heating, enhanced the immunogenic effect of the vaccines in mice, as evidenced by their increased resistance to challenge with lethal doses of homologous and heterologous strains of dysentery bacilli (Shigella flexneri and Shigella sonnei). Studies on the antigenic effect of prodigiosan with the vaccine combination showed no significant differences among test and control animals.

- 63 CHARACTERIZATION OF "CLEARANCE" FACTOR AND "CELLBOUND" ANTIBODY IN EXPERIMENTAL TYPHOID. (E.) Ushiba, D. (Keio U. Sch. Med., Tokyo), T. Nakae, T. Akiyama and Y. Kishimoto. J. Bact. 91(5):1705-1712, 1966.

Serum of rabbits which were immunized with a killed vaccine of an S-type virulent strain of Salmonella enteritidis produced a "clearance" factor identified as O agglutinin and characterized as a class of macroglobulin with a sedimentation coefficient of 12.7S. This macroglobulin showed a single protein peak with electrophoresis and its agglutinin and "clearance" activity was inactivated both by mercuric ethanol treatment and absorption with the specific O antigen. The H agglutinin was also isolated as a single globulin fraction which had no "clearance" activity and was characterized as a 7S γ -globulin. Urea extracts of cells from mice immunized with the S-type killed vaccine contained a macroglobulin similar to that described in the rabbit serum. This was not found in cells of mice immunized with a live vaccine (R-type mutant) which indicates that the effect of the "cellular" immunity in experimental typhoid produced by the R-type live vaccine is not due to "cell-bound" antibody with "opsonic" activity.

- 64 ANATOMIC ADAPTATION OF THE ALIMENTARY TRACT OF THE RAT TO THE HYPERPHAGIA OF CHRONIC ALLOXAN-DIABETES. (E.) Jervis, E. L. (U. Sheffield, England) and R. J. Levin. Nature (London) 210(5034):391-393, 1966.

The diameter, length and dry wt. of the small intestine taken from chronic alloxan-diabetic (60-70 mg/kg i.v. of alloxan) rats are markedly greater than that of the control rats which were either the same weight or age (6-12 mo.). A small increase in stomach weight is also noted in the diabetic rat. The wt. of the cecum remained unchanged. Even though the diabetic rats ate 2-3 times more food than the controls, these intestinal changes are not caused by bulk per se as they were not observed on rats which received a diet bulked-out with talc. The nutrient/intestinal absorptive surface ratio is discussed as a possible explanation of these changes seen in the digestive tract of chronic alloxan-diabetic rat.

- 65 SPECIES DISTRIBUTION OF GASTROINTESTINAL ANTIGENS. (E.) Nairn, R. C. (Monash U., Melbourne, Australia) and W. G. R. M. De Boer. Nature (London) 310(5039):960-962, 1966.

Immunofluorescent technics were used to detect the presence of gastrointestinal antigens in over 80 mammals (12 species of placentals, 8 species of marsupials, and 2 species of monotremes) and in 25 species of other vertebrate classes. Two types of antisera were used: one from rabbits immunized with human colonic mucosa and one obtained from pernicious anemia patients containing naturally occurring autoantibody to human gastric parietal cells. Tissues taken within 1 hr. of death were stained by direct immunofluorescence (rabbit serum conjugated with lissamine rhodamine B) or by the sandwich method (pernicious anemia serum) using rhodamine B-conjugated anti-human globulin. Antigens were found only in mammals. With the rabbit antiserum, staining was obtained 1) in the colons of all adult mammals and of human fetus and lamb; 2) in the small intestine of all adult placentals and the human fetus, but in only 2 marsupials and in no monotremes; and 3) in the stomach of man (including the fetus), monkey, and pig. The reaction was strongest in the colon, less in the small intestine, and weakest in the stomach. The most intense staining was given with the homologous (human) mucosa; it was strong in monotremes and non-human placentals except rodents, which had a weaker reaction comparable to that of the marsupials. With the pernicious anemia serum, staining was limited to parietal cells and occurred in all placentals and marsupials tested, being more intense in placentals, with no species differentiation. The findings were further confirmed by serum absorption studies.

- 66 SYNDROME OF INTESTINAL ARTERIAL INSUFFICIENCY ("ABDOMINAL ANGINA"). (E.) Bircher, J. (Mayo Clin., Rochester, Minn.), L. G. Bartholomew, J. C. Cain and M. A. Adson. Arch. Intern. Med. (Chicago) 117(5):632-638, 1966.

Chronic ischemia of the intestine is described in 9 primary cases with atherosclerotic disease and in 6 cases where the condition is secondary to other diseases which compromise arterial blood supply. The two categories appeared to be indistinguishable with respect to age or symptoms; the latter most commonly being abdominal pain which

GENERAL

was exacerbated by eating and, consequentially, anorexia. In all cases the superior mesenteric artery or one of its major branches was always involved. The ratio of men to women was 4:1 and their av. ages were 56 and 47.3 yr, resp. Generally, neither roentgenologic examination nor laboratory data proved helpful in differential diagnosis except that the sulfobromophthalein retention test, performed in seven cases, gave abnormal results in four. The most promising diagnostic finding was the early localization of a systolic bruit of high frequency and short duration. With early diagnosis, successful surgical bypasses were performed.

- 8567 BURSTING PRESSURE OF HEALING GASTROINTESTINAL WOUNDS IN THE RAT. (E.) Scheinin, T. M. (U. Turku, Finland) and J. Viljanto. Ann. Med. Exp. Fe 44(1):49-51, 1966.

Bursting pressure of healing gastrointestinal wounds (stomach, duodenum, ileum and cecum) of adult Wistar rats were measured and compared with controls from postoperative day 1-10. During the first 2 days approx. similar values were observed in all wounds as resistance to increased intraluminal pressure did not increase during this time (food was not allowed until day 2). After postoperative day 3, the strength of duodenal and ileal wounds increased rapidly and attained the strength of intact walls within 7 days. Healing of gastric and cecal wounds was slower and normal strength was not attained until postoperative day 10. The final resistance in the various wounds had no definite correlation with the thickness of the intestinal wall; rather, the gastrointestinal segments with a wide lumen showed a low resistance to increased intraluminal pressure.

- 8568 ANTIBODY RESPONSE AFTER IMMUNIZATION WITH TYPHOID-PARATYPHOID A AND B VACCINE IN KALA-AZAR. (E.) Cassimos, C. (U. Athens, Greece), S. Lazanakis and T. Thomaidis. Acta Paediat. Scand. 55(3):301-304, 1966.

Anti-H antibody response is much below normal in patients suffering from Kala-azar disease, following typhoid-paratyphoid A and B (I) immunization. The ages of the 12 patients studied ranged from 1-12 yr. (as did the matched controls) and the doses were appropriately adjusted. Prior to immunization, there was no agglutinin activity against I in either the patients or the controls. Anti-O agglutinin was absent (or nearly so) in both groups after immunization while good agglutinin activity against H antigen occurred only in the controls. Anti-TH titers were particularly low after the second vaccination in the patients but this improved after the third immunizing dose. This was probably a reflection of a positive response to treatment with glucantime. These results seem to indicate that the high γ -globulin levels seen with Kala-azar are the result of the production of an abnormal γ -globulin.

- 8569 CLINICAL STUDIES ON TYPHOID FEVER IN THE PRE-ANTIBIOTIC AND ANTIBIOTIC ERA. STATISTICAL STUDIES. (It.) Rondanelli, E. G. (U. Pavia, Italy), P. Gorini, G. Casirolo and G. C. Morandini. Gior. Mal. Infett. 17(7):392-411, 1965.

Clinical signs and symptoms of typhoid fever were compared in 925 patients hospitalized prior to the era of chloramphenicol treatment (January, 1945, to May, 1949) (I) and during the era when chloramphenicol was admin. (June, 1949, to December, 1963) (II). Sudden onset of fever with chills was more frequent in II than in I; sudden onset without chills was the most frequent form in both periods, although it occurred in less than 50% in II. Tongue alterations, stupor, and hepatomegaly were more frequent in II; abdominal pain, ileocecal congestion, roseolar spots, and splenomegaly were less frequent; bradycardia was equally frequent in both periods. Changes in the frequency of clinical signs and symptoms were usually more pronounced during the active phase; the increased incidence of stupor in II, however, was more pronounced during the first wk. of illness. In II, abdominal pain, ileocecal congestion, and hepatomegaly markedly increased during the later stages of disease, while tongue alterations and stupor were relatively decreased. The authors point out that the relatively late date at which patients are hospitalized in II may create difficulties in the diagnostic confirmation of various clinical signs.

- 8570 ANALYSIS OF RECURRENCES IN ABDOMINAL TYPHOID AND PARATYPHOID FEVER PATIENTS TREATED WITH AND WITHOUT CHLOROMYCETIN, WITH AN EXAMINATION OF

WIDAL REACTION TITERS. (Ger.) Jeżyna, C. (Hosp. Infectious Dis., Biały-stok, Poland), D. Prokopowicz and H. Tomaszko. Arch. Hyg. 150(1/2):125-134, 1966.

Among patients with abdominal typhoid and paratyphoid fever who were treated with chloromycetin (chloramphenicol; total doses = 10-50 g), 20 of 160 experienced recurrences within 4-13 days. In 13 of 20, the total dose ranged from 14-20 g; in 7 of 20, from 21-28 g. There were no recurrences among 51 other patients treated with the same drug in total doses of less than 10 to 20 g; among 63 other patients receiving total doses of 21-30 g; or among 26 patients receiving total doses of 31-50 g.

Among a control group of patients receiving only symptomatic treatment, recurrences were seen in 6 of 103. In a majority of treated patients with recurrence, the Widal Reaction titer (as compared to the highest titer recorded prior to initiating treatment) was decreased after treatment with chloramphenicol, increased again within a few days after medication was withdrawn. This was interpreted as a specific effect of the drug on the underlying mechanism of action involved in the test.

571 A NEW HYPOTHERMIA UNIT FOR THE CONTROL OF GASTROINTESTINAL BLEEDING. (E.) Weeder, R. S. Bull. Geisinger Med. Ctr. 18(2):51-60, 1966.

Following decreased acid-pepsin activity, inhibition of acid secretion, inhibition of histamine granule release, reduction of gastric blood flow, and decreased gastric motility as the benefits of cooling for treatment of bleeding in the upper gastrointestinal tract, an inexpensive simple gastric cooling unit was devised. The unit consisted of a reservoir, air trap, cooling coil (immersed in ice), an intragastric balloon attached to a double lumen tube, and a centrifugal pump to circulate the cooling liquid (saline). In use a temperature of approx. 15°C. was maintainable. The apparatus was used to treat 5 patients with gastric bleeding, in each case bleeding stopped, hematocrit values increased, additional transfusions were unnecessary, body temperatures were stabilized, and pulse rates decreased. Eleven additional patients were successfully treated with this apparatus after presentation of this report.

572 EFFECT OF HOT PEPPERS ON GASTROINTESTINAL TRACT. (E.) Mitkov, D. (Pavlov Higher Inst. Med., Plovdiv, Bulgaria) and H. Milenkov. Folia Med. (Plovdiv) 8(2):67-71, 1966.

Fifteen white rats receiving daily 10-15 ml milk infusion of hot dry peppers "Julinska shipka" (0.3-1 g) in addition to their daily diet for 12 mo. were compared to 10 animals receiving the same diet without the peppers. Compared to controls the experimental animals showed an increase in collagen in the submucosa particularly in the duodenum and upper intestine, an increase in PAS-positive substances in the stomach mucosa, increased lipase activity in the gastrointestinal mucosa and an increase of alkaline phosphatase in the intestine. Fatty infiltration of the liver of the experimental animals was believed correlated with the deposition of fats in the gastrointestinal mucosa.

573 RETICULOCYTIC LYMPHADENITIS WITH ABSCESS FORMATION - MASSHOFF'S DISEASE. (Ger.) Kühn, H. (St. Georg Hosp., Leipzig, Germany). Zschr. Gastroent. 4(1):36-44, 1966.

Among 61 patients with reticulocytic lymphadenitis with abscess formation, the disease was seen almost exclusively in patients aged 5-19 (peak incidence between 10-14). The youngest was 4; only 5 cases occurred between age of 20-30 and only 1 thereafter (a man age 51). The male:female ratio was 48:13. Diagnosis could not be established preoperatively, the clinical picture resembling that of appendicitis. The presence of *Pasteurella pseudotuberculosis*, Type I, was demonstrated in 2 of 8 mesenteric lymph nodes examined bacteriologically and a majority of patients reported prolonged, direct contact with cats, dogs, birds and other animals known to be carriers of this organism. The author discusses the possibility of infection resulting from play with such animals or in places where they have voided, pointing out that this organism is contained in both urine and feces.

574 SURGICAL PROBLEM OF ABDOMINAL TUBERCULOSIS. (Hun.) Mester, E. and T. Sági. Magy. Sebész. 19(1):1-9, 1966.

ESOPHAGUS

- 735 THE IODINE TEST OF SCHILLER AS A DIAGNOSTIC TOOL FOR CONDITIONS OF THE ESOPHAGUS. (Ger.) Voegeli, R. (City Hosp., Basel, Switzerland). Pract. Otorhinolaryng. (Basel) 28(3):230-239, 1966.
- The intense color reaction (deep brown staining in situ) produced upon application of 2% Lugol solution to the normally glycogen-rich epithelium of the human esophageal mucosa has been shown to be a valuable diagnostic tool. In all 10 cases undergoing endoscopic removal of foreign bodies from the esophagus, the iodine (I) solution applied to 3 selected regions (cervical, middle thoracic and cardial regions of the esophagus) produced the intense brown coloration characteristic of normally present intraepithelial glycogen. Occasional small I-negative plaques showed up as sharply defined colorless spots. The transitional zone (Z-line) between gastric and esophageal mucosa was clearly visualized in each case. In 19 cases of reflux esophagitis of various stages, color intensity was shown to depend on the degree of existing cellular involvement. In 1 of 4 cases with no endoscopically demonstrable symptoms, coloration of the middle and distal esophageal portions was weak. The Z-line was well marked. The same was found in 4 cases with moderate hyperemia of the mucosa, while in 5 cases of edematous, fibrous and hyperplastic esophagitis the mucosa remained pale or completely iodine-negative. Only in 3 of 5 cases was the Z-line still identifiable. In one of the above 5 cases, a very weak reaction was found in the upper region reaching 30 cm only from the dental line, and continuing abruptly as a completely I-negative epithelium. The diagnosis of brachyesophagus was demonstrated by biopsy. In 6 cases of eroding, hemorrhagic and ulcerative esophagitis, the entire lining was pale or I-negative, all wound areas being completely negative. In only 1 of 6 cases could the Z-line be weakly seen. In one case, general examination revealed an extremely small epithelial carcinoma of the uvula which could not be considered as the primary tumor. X-ray study of the upper digestive tract revealed only a small diverticulum. Endoscopy was also negative. However, the I test revealed immediately distal from the diverticulum entrance a sharply defined, lentil-sized I-negative spot. Histologically, it represented a highly atypical squamous epithelium with polymorphic and heterochromatic nuclei, layered over the mucous membrane in various stages of infiltration.
- 736 OBSERVATIONS ON THE NATURE OF THE STRICTURE IN BARRET'S ESOPHAGUS (ALLISON AND JOHNSTONE'S ANOMALY). (E.) Seaman, W. B. (Columbia U. Coll. Phys. Surg., New York, N. Y.) and R. H. Wylie. Radiology 87(1):30-32, 1966.
- Two cases of symptomatic patients with columnar-lined esophagus associated with a stenosis at the site of mucosal transition are presented. In each case, the stenosis was demonstrated both radiologically and by esophagoscopy. Hiatal hernia was also present in both patients. In both, the stenotic areas improved markedly after repair of the hiatal hernia without specific treatment being directed to the sites of narrowing. No visible or palpable thickening of the esophagus or peri-esophageal tissues was found at operation. Muscular spasm associated with esophagitis is suggested as a possible explanation.
- 737 ESOPHAGEAL MOTILITY STUDIES. (E.) Hansky, J. (Monash U. Sch. Med., Melbourne, Australia). Aust. Ann. Med. 15(2):129-135, 1966.
- Using water-filled, open-ended tubes connected to external strain gauge transducers, a study of the propulsive and pressure characteristics of the esophagus and its sphincters (made on 8 normal subjects and 56 who presented esophageal symptoms) suggested that this method permits precise diagnosis of esophageal neuromuscular disorders and differentiation of these from suspected organic obstruction. Of the 64 patients, there were 22 with normal motility, 14 with hiatus hernia, 11 with diffuse spasm, 7 with achalasia, 7 with scleroderma and 4 with obstructive dysphagia. The following was diagnostic for diffuse spasm: high amplitude, repetitive simultaneous contractions either occurring spontaneously or following deglutition and no response to methacholine. Achalasia cases presented a high resting pressure and normal motility in the body of the esophagus, along with a positive response to methacholine. Scleroderma was differentiated from the achalasia by the finding of low resting esophageal pressure and a negative methacholine response.

- 8738 EXPERIMENTAL REFLUX ESOPHAGITIS. (E.) Lippa, F. H. (Wayne State U. Sch. Med., Detroit, Mich.) and A. P. Thal. *Arch. Surg. (Chicago)* 93(1):148-150, 1966.

Hiatal hernias were surgically created in 24 dogs in studies aimed at ameliorating established reflux esophagitis. Positive pressure respiration was applied, the peritoneal cavity entered, the hiatal esophageal ring incised and the stomach mobilized. One half was brought into the chest and sutured to the right crus. Seven dogs were fluoroscoped 4 wk. after surgery; no reflux of contrast material into the esophagus was seen despite considerable gastric retention. Seven dogs with hiatal hernia introduced as above were subjected to Wendel cardioplasty (to destroy the cardiac sphincter) and Jaboulay gastroduodenostomy; after recovery, animals were fluoroscoped and all showed free reflux of gastric contents into the duodenum. Having established a preparation with proved esophageal reflux, these dogs were then reoperated using fundoplication procedure. After recovery, dogs were fluoroscoped, and 6 of 7 had no reflux; the one failure was due to an error in technic. At autopsy 4 wk. later, 6 dogs showed normal esophageal and gastric tissues. Cardioplasties and hiatal hernias were performed in 10 dogs, of which 5 served as controls and 5 had a fundic fold procedure. All were given i.m. histamine (30 mg/day). The dogs were sacrificed after signs of esophageal or gastric ulceration, usually 4-8 days after starting histamine. In the 5 dogs with fundic folds, there was no evidence of esophagitis, yet all 5 dogs showed evidence of hypersecretion as evidenced by antral or duodenal ulcers and melena. The fundic fold seems to be quick, simple and physiologic, creating a substitute sphincter in animals. Early clinical results confirm the value of the method.

- 8739 STUDIES ON THE ARTERIO-VEINUS RELATIONSHIP IN THE TRANSITIONAL ZONE BETWEEN THE STOMACH AND THE ESOPHAGUS IN MAN. (Ger.) Ferraz de Carvalho, C. A. (U. Sao Paulo Sch. Med., Brazil). *Anat. Anz.* 118(4):261-280, 1966.

This is a detailed microscopic-anatomic study of blood supply in the histologic transitional zone between esophagus and stomach of 92 autopsy specimens (subjects of both sexes, ages 12-90). The specimens were inj. either with gelatin, containing Cinnabar or India ink (for arterial and venous contrast), or with barium sulfate; the latter were inspected radiologically and the former were "diaphanized" (Spalteholz method). The arterial systems were developed in 52 specimens, the venous systems in the rest. Six of the latter group were later used for histologic studies, the slides having been stained with haematoxylin and eosin, Giesons, or the Calleja method. Important morphologic differences between the arterial and venous systems were found especially in the esophageal zone. The arterial circulation is centrally oriented, i.e. from the superficial perimuscular arteries directly towards the deep regions, transversally through the tunica muscularis. Its corresponding venous system, deeply imbedded in the walls, follows the longitudinal axis of the organ, having very little communicating channels with the outer, superficial venous net. This complex longitudinal venous circulation is organized in the form of a "Rete Mirabile" (miraculous net), and its probable function is to compensate for regurgitation (stomach to esophagus), and also plays a regulatory role concerning the circulation between some segments of the portal and superior cava veins. Anatomically, the existence of such a distinctive blood flow pattern permits the classification of a 7-8-cm band around the transition line as a distinct morphologic-functional unit.

- 8740 EFFECTS OF MEDIASTINAL GRAVITY ON ESOPHAGEAL "ELASTICITY". (Fr.) Petit, J. M. (Leon Fredericq Inst., Liege, Belgium), C. Jacquemin, J. Damoiseau, P. Varenne and J. Troquet. *Rev. Med. Aero. (Paris)* 4(16):4-6, 1966.

The ability of the esophagus and surrounding tissues to absorb or damp intrathoracic pressure, known as esophageal "elasticity" (elastance) was tested in 5 healthy, adult males subjected to chest-back acceleration forces up to 7 g. Elasticity increased as an essentially linear function of the force of acceleration to which the mediastinum was subjected, confirming the participation of mediastinal inertia in creating the phenomenon. The increase of esophageal elasticity which accompanied increased acceleration did not interfere significantly with measurements of respiratory variations of intrathoracic pressure: in the presence of a coefficient (vol./pressure) of 1.10^{-3} ml per cm water, despite esophageal elasticity of 10 cm water per ml the indicated error in the final result was approx. 1%.

- 8787 MODIFIED METHOD OF SPLENOPORTOGRAPHY IN STOMACH CANCER. (Rus.) Granov A. M. (Donetsk State Inst. Med., USSR) and I. N. Khotomlianskaia. Vop. Onkol. 12(5):15-18, 1966.

Visually controlled splenoportography (with patient in vertical position) in combination with pneumoperitoneum was performed without any complications in 30 patients with gastric cancer (without splenomegaly). Determination of the extent of cancer spread beyond the limits of the stomach wall and prediction of inoperability were possible in 11 patients. The extension of cancer spread was revealed by the presence of a characteristic block indicative of changes in the configuration of vessels of the extrahepatic portal system and modifications of intrahepatic architecture. Characteristic findings with regard to cancer spread to lymph nodes of the splenic blood vessels, to the liver, and to the retroperitoneum are described. All pre-operative findings revealed by this method were confirmed at laparotomy. The practical importance of splenoportography in the determination of stomach cancer spread is stressed.

- 8788 HEIDENHAIN POUCH BLEEDING DUE TO ORAL SALICYLATES. (E.) Cooper, G. N., (Marquette U. Sch. Med., Milwaukee, Wis.), R. C. Meade and E. H. Ellison. Arch. Surg. (Chicago) 93(1):171-174, 1966.

Nine dogs with Heidenhain pouches were inj. with radioactive chromium-tagged RBC to measure bleeding after the p.o. admin. of salicylate in 3 treatment periods. Period 1 (5 days): 5 dogs received acetylsalicylic acid and 4 received choline salicylate total salicylate 70 mg/kg day; Period 2 (4 days): same as period 1 except drug dosage was increased to 140 mg/kg/day; Period 3 (5 days): all 9 dogs plus 2 additional received acetylsalicylic acid (140 mg/kg/day). Pouch bleeding during Period 1 was not significant. During Period 2, pouch bleeding increased significantly in 3 of 9 dogs given acetylsalicylic acid but not in those given choline salicylate. In Period 3, bleeding in 6 of 11 dogs increased significantly. After each period, when salicylate was discontinued, pouch bleeding dropped to pretreatment levels. Autopsies showed ulcerations in some pouches and superficial erosion in others. Acetylsalicylic acid ingestion in dogs leads to bleeding from isolated gastric pouches which is dose-related.

- 8789 PERIPHERAL NERVE CHANGES IN THE REGION OF GASTROINTESTINAL ANASTOMOSIS DURING OPERATIONS WITH AND WITHOUT THE USE OF RIGID CLAMPS. (Rus.) Tikhii, A. T. (Dnepropetrovsk Med. Inst., USSR) and E. M. Kimbarovskaia. Klin. Khir. (Kiev) (3):24-28, 1966.

A total of 28 dogs were subjected to gastrointestinal anastomosis by the Hofmeister-Finsterer technic without rigid clamps (Group 1) or by the Hofmeister-Finsterer-Kimbarovskii technic using Pair clamps (Group 2). Two days after surgery, 3 types of neural elements were observed: (1) disintegrated neural cells and filaments provoked by surgical trauma; (2) altered neural elements induced by reactive processes; (3) regular neural cells and filaments. By day 3, Group 1 showed no improvement in the region of anastomosis, while regenerating nerve filaments were observed in animals of Group 2. By day 7-10, slight changes were seen in Group 1, while animals of Group 2 showed a progressively increasing number of regular filaments and several peripheral nerve formations. By day 15, Group 1 showed small numbers of regenerated filaments, while the number of regular filaments increased and a single layer of epithelium was observed in animals of Group 2. In Group 1, the anastomotic region was well innervated and peripheral nerve elements were of normal appearance after 12 mo., while in Group 2 the anastomotic region assumed a normal appearance within 3 mo. It is concluded that following gastric resection and the use of rigid clamps, epithelialization of the mucosa and regeneration of peripheral nerve filaments in the anastomotic region occurred significantly earlier than when surgery was performed without the use of clamps.

- 8790 THE PANCREOZYMIN-SECRETIN TEST AFTER PARTIAL GASTRECTOMY. (E.) McGillivray, D. C. (Shaughnessy Hosp., Vancouver, Canada), S. N. Stordy and A. Bogoch. Canad. Med. Assn. J. 94(24):1261-1263, 1966.

OMACH

17 patients with previous partial gastrectomies and no evidence of exocrine pancreatic insufficiency, fasting i.v. admin. of pancreozymin, followed 10 min. later secretin, failed to raise serum amylase or serum lipase activity above normal levels and in most cases, failed to affect it at all. A similar lack of response was exhibited by non-gastrectomized controls. One additional gastrectomized patient, whom basal serum lipase activity was above normal, showed a moderate decrease at the end of the first hr., followed by an increase to above the basal level at the end of hr. 2 and 4, both in the absence of any change in serum amylase value. In control subjects, measurements of volume, bicarbonate conc. and amylase and lipase activity in duodenal aspirates showed a very wide range of basal values and responses to the test. It is concluded that the diagnostic value of this technic is at least very limited.

91 MODIFICATIONS OF THE BACTERIAL FLORA OF THE GASTROINTESTINAL TRACT OF THE RAT, FOLLOWING GASTRECTOMY OR GASTRIC SHUNT. (Fr.) Lambert, R. (U. Lyon Sch. Med., France), S. Chassignol, A. Sedallian, L. Descos and F. Martin. C. R. Soc. Biol. (Paris) 159(12):2435-2439, 1965.

In rats which had undergone total gastrectomy or esophageal-jejunal anastomosis, a significant increase of the absolute number of bacteria normally seen in the gastrointestinal tract was in evidence, increasing progressively as regions were assayed in an aboral direction. Affected were Lactobacillus, Streptococcus fecalis and Escherichia. In addition, Staphylococcus aureus and Proteus bacilli were encountered in the colon and small intestine of animals with gastric shunt; in the jejunum, ileum and cecum, in gastrectomized animals. Peroral treatment with oxytetracycline resulted in virtually total suppression of the abnormal bacteria in both groups of animals, although some Proteus bacilli continued to be seen in the jejunum of the animals with gastric shunt. In the gastrectomized animals, this was accompanied by a sharp increase of the number of Lactobacilli, Streptococcus fecalis and Escherichia in the cecum, reaching 100 times the number found in intact animals, without significant increase in other areas of the gastrointestinal tract. In animals with a gastric shunt, a similar increase in the cecum was accompanied by a significant decrease of the number of each type appearing in the stomach, duodenum, jejunum and ileum. The authors conclude that a direct relationship existed between the presence of Staphylococcus aureus in the gastrointestinal flora and the presence of anemia in these animals.

792 ROLE OF ACETYLCHOLINE IN ALLERGIC PROCESSES AT THE GASTRIC MUCOSAL LEVEL. (Fr.) Groza, P. (D. Danielopolu Inst. Norm. Path. Physiol., Bucharest, Rumania), M. Corneanu and L. Rusovici. Rev. Roum. Physiol. 3(1):55-59, 1966.

Four dogs with Pavlov pouches were sensitized with horse serum, 5.0 ml i.m. and 1.0 ml i.v., 3-4 times at 1-2 day interval. Alimentary excitation was achieved with 100 g of fresh calf lung. Acetylcholine (per ml), cholinesterase (μ M) and mucopolysaccharides (mg%) were determined in both the gastric juice collected in the first hr. of sensitization, and in the blood or serum, resp. In addition to an inconclusive increase in gastric juice volume, gastric acetylcholine increased significantly in all 4 dogs; cholinesterase decreased in 3 of 4. Blood values of the latter showed a tendency to decrease; mucopolysaccharides increased slightly.

793 INVESTIGATIONS ON THE ROLE OF ACETYLCHOLINE IN ALLERGIC PROCESSES AT THE LEVEL OF THE GASTRIC MUCOSA. (Rum.) Groza, P. (Physiol. Inst. Rum. Acad. Sci., Bucharest), M. Corneanu and L. Rusovici. Fiziol. Norm. Pat. 12(3): 193-198, 1966.

Report in Rumanian of no. 8792.

794 DEVELOPMENT OF CHRONIC GASTRITIS BASED ON AN IMMUNOLOGIC MECHANISM. (Cz.) Fixa, B. (Charles U., Hradec Kralov, Czech.), O. Vejbor, O. Komárkova, V. Herout, F. Langr, F. Pařízek and J. Prixova. Cas. Lek. Cesk. 105(11): 279-283, 1966.

STOMACH

Autoimmune antibodies (I) against their own tissue (gastric mucosa obtained by biopsy) were determined by the Gajdusek Complement-Fixation Test in 140 patients. Among patients with normal gastric mucosa (controls), no I were found. Among 40 patients with superficial gastritis, 7.5% showed I; among 9 patients with gastritis of undetermined type, 11.1% had I; among 55 patients with atrophic gastritis, 23.6% had I. The incidence of I was similar both in male and female patients with atrophic gastritis. A review of pertinent literature is included. It is concluded that the immunological mechanisms may play an important role in the pathogenesis of chronic gastritis.

- 8795 ETIOLOGIC AND PATHOGENETIC CONSIDERATIONS IN PERNICIOUS ANEMIA. (Dut.) Te Velde, K. (Natl. U., Groningen, The Netherlands) and P. J. Hoedemaeker. I. Gastroent. 9(2):129-142, 1966.

Circulating antibodies against parietal cells were found in 87% of patients with pernicious anemia; in only 3% of normal controls. They were also found in 24% of the close relatives of such patients, in contrast with 5% of a control group of persons marrying into these families. Further study of serum vitamin B content and Schilling Test data among the patients' relatives with these antibodies, as well as studies of their gastric secretions and mucosa, suggested that these syndrome components, like the presence of circulating intrinsic-factor antibodies, constitute a single system of secondary manifestations within the pleiotropic manifestation pattern of one major, autosomal, dominant gene; with the full development of pernicious anemia representing an intensified, or far-advanced, expression of the operation of this genetic factor. If so, an intermediate expression of the same appears to be evidenced in the familial, chronic gastritis associated with the presence of these same anti-parietal-cell antibodies. (See no. 8796.) The primary, normal-range expression of the genetic factor in question is not yet clear. It is also pointed out that an autoimmunologic process may be an important etiologic factor in the development of both the familial gastritis and pernicious anemia, since the histologic appearance of the gastric lesions in the final stage (pernicious anemia) is similar to that seen in lesions of the thyroid in Hashimoto's disease and organ-specific antibodies are also demonstrable there.

- 8796 MORPHOLOGIC AND FUNCTIONAL CONSIDERATIONS IN CHRONIC GASTRITIS IN PATIENTS WITH CIRCULATING ANTIBODIES AGAINST PARIETAL CELLS. (Dut.) Hoedemaeker, J. (Natl. U., Groningen, The Netherlands) and K. Te Velde. I. Gastroent. 9(2):143-155, 1966.

Comparative morphologic and functional studies of the gastric mucosa were undertaken for 3 groups of achlorhydric patients. Diffuse atrophic gastritis was found in 18/19 with pernicious anemia; 41/50 with circulating antibodies against parietal cells, and in only 2/33 who did not have such circulating antibodies. Comparable tabulations for total gastric atrophy were 11/29, 9/50 and 0/33, resp.; for superficial gastritis - 0/29, 0/50 and 5/33, resp.; for chronic multifocal gastritis - 0/29, 0/50 and 26/33, resp. In Schilling's Test, the presence of the circulating antibodies was accompanied by a marked shift to the left, with values 5% or less tabulated as 29/29, 11/50 and 0/33, resp.; of 5-15%, as 0/29, 20/50 and 3/33, resp. of 15% or more, as 0/29, 19/50 and 23/33, resp. The authors conclude that the familial chronic gastritis which is associated with circulating antibodies against parietal cells may lead to pernicious anemia as an end-state. The probable course of development involved is detailed in the light of biopsy and other records of various subgroups of the study population. (See also no. 8795.)

- 8797 DIGESTION AND ABSORPTION FOLLOWING GASTRECTOMY USING REVERSED JEJUNAL SEGMENTS: FOLLOW UP OF 50 CASES. (E.) Poth, E. J. (U. Texas Med. Br., Galveston) and L. B. Smith. Ann. Surg. 163(6):957-960, 1966.

Among patients in whom gastric substitution was made by construction of a pouch from jejunal loops, following gastrectomies ranging from 50% to total, 23 of 50 were surviving at the time of report. The highest mortality rate (23/29) was seen among patients with gastric neoplasms. Diarrhea was avoided and slowing of passage time was ensured by construction of a short, antiperistaltic outlet segment. Occasional

OMACH

or absorption of vitamin B₁₂, when more than 5% of the proximal stomach was re-
 ined, emphasized the need for testing absorption within 6 mo. postoperatively and
 en at yearly intervals, in view of the possible loss of capacity to produce in-
 insic substance in the presence of progressive gastritis. Triolein uptake in 17
 rvivors ranged from 6.5-24.0% (6.0% = normal). The highest rate was seen in a
 tient who had undergone total gastrectomy and a 95% pancreatectomy, although, for
 e group as a whole, the indicated efficiency of fat digestion was attributed to
 th deceleration of the rate of passage through the pouch and regurgitation of
 ncreatic substance into the pouch before the food entered the duodenum. Blood
 lumen levels were consistently equal to or above normal. In almost all cases,
 otein digestion was essentially normal and nutrition appeared to be excellent un-
 r ordinary conditions of alimentation.

98 ALBUMIN LOSS IN EXPERIMENTAL GASTRITIS. (E.) Rodriguez Ollerios, A. (U.
 Puerto Rico, San Juan), S. Irrizarry and M. I. Rivera. Bol. Asoc. Med. P.
 Rico 58(3):102-111, 1966.

en 26 μ c of I¹³¹ albumin was admin. i.v. to 7 dogs with experimental gastritis,
 e av. total radioactivity in the gastric juice was 1.66% of the dose and the dis-
 pearance half-time was 5.5 days. Three types of gastritis were induced: serous
 stritis produced by creosote-diol; erosive gastritis produced by atophan; and
 pillomatous gastritis produced by croton oil. With the 3 control dogs, the al-
 min I¹³¹ turnover was less rapid with a half-time of 7.7 days and only 0.47% of
 e original dose appeared in the gastric juice. The av. volume of gastric juice
 creted in a half-hour was 66 ml for the controls and 114 ml for the experimental
 gs. Thus, the increased turnover of albumin which occurs with gastritis is far
 eater than can be explained by mere increased volume of gastric juice.

99 CARCINOID SYNDROME WITH GASTRIC HYPERSECRETION AND HISTAMINURIA. (E.)
 McGill, D. B. (Mayo Clinic, Rochester, Minn.) and H. R. Jones, Jr. Arch.
 Intern. Med. (Chicago) 117(6):784-788, 1966.

57-year-old woman presented certain typical features of the carcinoid syndrome:
 etastasis in the liver with diarrhea and spontaneous flush. Contrary to the usual
 elineation of this syndrome, she neither flushed nor exhibited a depressor response
 th doses of epinephrine as high as 10 μ g i.v. In addition, marked histaminuria
 nd gastric hypersecretion (about 10 times normal) were demonstrated, but there was
 o duodenal ulcer, nor steatorrhea. The ratio of basal acid secretion/maximal stim-
 lated values was 78% which is well within the range of positive diagnosis for
 illinger-Ellison syndrome. Abdominal exploration failed to disclose a primary le-
 ion; skin tests for tuberculosis and allergy were negative. Roentgenograms indi-
 ated that the primary lesion was probably in the lung. Nasal and periorbital con-
 estion, wheezing and diarrhea did not respond to treatment and death eventually
 issued.

300 THE OLYMPUS GTF CAMERA GASTROSCOPE AND THE OLYMPUS GT5 STANDARD GASTRO-
 CAMERA. THE REALM OF THE RADIOLOGIST. (E.) Kalokerinos, J. (Royal North
 Shore Hosp., Sydney, Australia). Aust. Radiol. 10(1):39-44, 1966.

comparison of the Olympus GTF, the Olympus GT5 and the Hirschowitz gastroscope led
 o the selection of the Olympus GT5 as the instrument of choice for photographs of
 e stomach. With the GT5, satisfactory photographs of the whole of the stomach
 ere obtained in 60.4% of 58 patients with various gastric lesions. The examination
 as well tolerated and only required a few minutes. The GTF gave satisfactory
 otographs in 74.5% of 14 patients examined but they were selected favoring the
 TF in that it does not show lesions close to the cardio-esophageal opening and it
 s the instrument of choice for showing stomata. The GTF was preferred to the
 irschowitz gastroscope because of its smaller size and its capacity to make more
 otographs. However, the GT5 is the least expensive.

801 CLINICAL AND MORPHOLOGICAL COMPARISONS IN STOMACH POLYPOSIS. (Rus.)
 Smirnov, N. M. (Inst. Oncol., Acad. Med. Sci. USSR, Leningrad) and T. V.
 Shemiakina. Vop. Onkol. 12(2):3-7, 1966.

linical and morphological studies were performed in 177 (81 men and 96 women; age
 9-72 yr.) of 250 patients with gastric polyps treated from 1926-63 at the Oncologic

Institute. The adenomatous polyps were classified as simple in 69 patients, proliferating in 36, and malignant in 72. Symptoms included pain in 125 patients, peptic disturbances in 140, and general disturbances in 31; no significant differences were observed with regard to type of polyp. Among 161 patients examined, achlorhydria was observed in 158, hypochlorhydria in 1, and normochlorhydria in 2. Among 76 patients tested, HCl secretion was normal in 17 and decreased in 59. Total digestive capacity was decreased in 65 and normal in 2. No significant difference in gastric mucosa were noted among the various types of polyps. In most patients, stable achlorhydria and functional disturbances of the gastric mucosa corresponded morphological changes in the polyps.

- 8802 GASTRIC RESECTION FOLLOWED BY PLASTIC RECONSTRUCTION USING SHORT ANTIPERISTALTIC SEGMENTS OF THE SMALL INTESTINE. (Rus.) Rotkov. I. L. (Gor'kiy Med. Inst., USSR). Eksp. Khir. Anest. 11(2):21-24, 1966.

Following antiperistaltic inclusion of a jejunal segment 10-12 cm in length between the gastric stump and the duodenum, 5 of 7 dogs survived; post-surgical course was without complications in 4 of 5; vomiting regressed after the first wk. Of 8 dogs subjected to antiperistaltic inclusion of a 4-5 cm-long jejunal segment, 5 survived but regurgitation was observed during the first days; no vomiting occurred after feeding of milk and water. In both groups, X-ray studies at the end of the first mo. showed delayed evacuation which became complete after 5-6 hr. After 6 mo., body wt. was stabilized, vomiting regressed, food intake increased, and the general condition improved. Animals with the shorter segment and with 50% capacity preserved were in better condition than the other animals. A technic using antiperistaltic inclusion of a 4-5-cm jejunal segment between the gastric stump and the duodenum was used in 33 patients with gastric (13) or duodenal ulcers (12), polyposis, or gastric cancer (8). Post-surgical course was similar to that observed after the Hofmeister or Finsterer technic. Acute symptomatology at the anastomotic site occurred in 1 patient, but by day 10-12 his condition was improved and evacuation was good. Other patients showed no vomiting, regurgitation, or postprandial symptoms; appetite was good and wt. gain rapid. X-ray studies at day 16-18 revealed delayed evacuation. After 8 mo., the general condition was good; dyspeptic disturbances, regurgitation, and bitter taste were absent, and food intake was normal. The author recommends further clinical trials with this technic.

- 8803 THE RESULTS OF SURGICAL TREATMENT OF CANCER OF THE STOMACH. (E.) Zacho, A. (Finsen Inst., Copenhagen, Denmark) and K. Fischermann. Surg. Gynec. Obstet. 123(1):73-79, 1966.

From September 1948 to December 1963, 561 cases of cancer of the stomach, in most instances far advanced (42%) or proximally located, were observed at the Finsen Institute. In 248 patients (197 adenocarcinomas; 7 sarcomas), the tumor was removed surgically by distal (22.6%), middle (1.6%), or proximal (34.7%) resection and total gastrectomy (41.1%). During the last 10-yr. period, overall mortality following radical surgery was 9%; during the last 5 yr. it was 11% for proximal, none for middle and distal resection, and 8% for total gastrectomy. Of all patients subjected to surgery (including palliative and those who died in connection with the operation) 18% are alive after 5 yr. Of the patients who survived a radical operation, 41% survived for 5 yr. or longer. The survival rate was 9% in patients undergoing palliative resection.

- 8804 DEMONSTRATION OF ACID PHOSPHATASE IN GASTRIC JUICE AND ITS VALUE IN THE DIAGNOSIS OF GASTRIC CARCINOMA. (Ger.) Yoshida, Y. (U. Heidelberg, Germany). Langenbeck. Arch. Klin. Chir. 314(3):255-262, 1966.

The patient material tested in this study included 39 cases with gastric carcinoma, 2 each of gastric sarcoma and degenerated gastric polyp, 1 each with carcinomatous ulcer, semimalignant gastric neurinoma, and cancers of the head of the pancreas, 15 with gastric ulcers, 2 with chronic gastritis and 33 with duodenal ulcers; one each with duodenal adenoma, cholelithiasis and urinary bladder papilloma, and 2 patients without any gastric symptomatology (101 patients). Fasting gastric juice was taken before surgery, centrifuged 5 min at 1500 revolutions/min., the sediment smear air-dried for not more than 15 min., fixed with acetone at 4°C for 2 hr., rinsed carefully with distilled water, immersed for 5 min. in 0.01 M soln. of EDTA, rinsed in

OMACH

distilled water, then placed for 8 hr. in a fresh soln. of 2% lead nitrate (20 ml) 40 ml 3% Na- β -glycerophosphate + 120 ml distilled water + 20 ml acetate buffer at pH 8 (the soln. contains CaCl_2 in a 0.01 M conc.), incubated at 37°C for 8 hr., rinsed, then immersed for 2 min. in 1% ammonium sulfite, rinsed in tap water and dried. Counterstaining is not necessary. Enzyme activity is evaluated by intensity of developing black-brown color. In 33 of 41 (80%) gastric malignancies the test for acid phosphatase was positive, whereas evaluation of Giemsa-stained preparations showed 9 of 41 positive cases (22%), while 8 false negatives and a number of weakly false positive results (15%) were seen, strongly positive results were found exclusively in cases histologically demonstrated gastric carcinoma except for the earliest stages of carcinoma (*in situ*), 2 of 5 serous carcinomas and 6 of 24 adenocarcinomas. Additional data are included to show that the results are not affected by the presence of bile, food, mucus, or the variations of pH in the gastric juice.

- 805 TRENDS IN MORTALITY FROM CANCER, WITH SPECIAL REFERENCE TO GASTRIC CANCER IN ICELAND. (E.) Sigurjonsson, J. (U. Iceland, Reykjavik). J. Nat. Cancer Inst. 36(5):899-907, 1966.

Revised statistics on cancer mortalities in Iceland, back-dated to 1921, confirmed that gastric cancer had not been overdiagnosed to any significant degree, despite the fact that the incidence of male deaths due to gastric cancer continues to be higher in Iceland than in any other country of Western Europe and the mortality rate for females is equaled only in Finland and Austria. (However, these mortality rates for gastric cancer are exceeded, for both males and females, in Chile and Japan.) Iceland has shown a significant downward trend in this respect, for both sexes, beginning before 1950 and continuing through 1960-63 (the most recent data studied), with a compensatory increase of mortalities from cancer of the peritoneum or other digestive organs.

- 806 COLOR PHOTOGRAPHY WITH A GASTRIC CAMERA AS A COMPLEMENT TO X-RAY EXAMINATIONS OF THE STOMACH. (Sw.) Gabrielsson, N. (Karolinska Hosp., Stockholm, Sweden). Nord. Med. 75(26):739-742, 1966.

Intragastric color photography, following X-ray, permitted preoperative diagnosis and localization of 12 cases of gastric neoplasm (5 of 12 by X-ray; 10 of 12 confirmed histologically; 2 of 12 not operated), 6 cases of polypoid mucosa (5 of 6 picked up by X-ray; 2 of 6 confirmed histologically, including the case missed by X-ray), 25 cases of mucosal hypertrophy (21 of 25 picked up by X-ray; 5 of 25 confirmed histologically), 12 cases of mucosal atrophy (4 of 12 picked up by X-ray; 2 of 12 confirmed histologically), 5 pyloric ulcerations (3 of 5 picked up by X-ray; 2 of 5 confirmed histologically, including 1 of 2 missed by X-ray), 10 ulcerations of the corpus (9 of 10 picked up by X-ray; 1 of 10 confirmed histologically) and 2 cases of cicatrization of an old ulcer wound with contraction of the surrounding tissue (1 of 2 picked up by X-ray). Color photography was also the initial means of diagnosis and localization of 2 cases of mucosal hemorrhage, 2 of stomal ulceration and 8 of varices in the fornix of the gastric cardia (4 of 8 shown by X-ray as esophageal varices). Among 64 patients examined with this device, 3 experienced transient, subsequent vertigo; a number reported roughness and/or tenderness of the throat which lasted until the following day.

- 807 HISTOCHEMICAL STUDIES OF GASTRIC MUCOSA IN GASTRITIS AND PEPTIC ULCER. (It.) De Vita, U. (U. Milan, Italy) and M. Guarino. Arch. Ital. Chir. 91(5):545-557, 1965.

Histochemical studies (Hotchkiss-McManus, Alcian blue, combined Hotchkiss-Alcian blue, and Gomori) were conducted on gastric mucosa specimens obtained at surgery from 12 patients with gastric ulcer and 10 with duodenal ulcer and chronic gastritis. Goblet-cell metaplasia was more frequent in patients with gastric ulcer (8 of 12) than in those with duodenal ulcer (4 of 10). Intense Alcian-positive staining occurred in areas not proximal to the peptic ulcer, while Hotchkiss-positive staining was prevalent at the margin of the ulcer. This indicates the acid nature of gastric secretion in chronic gastritis and gastric ulcer. At the level of the ulcer margin, greater alkaline phosphatase density was observed in the glandular epithelium as well as in the capillary endothelium. This increase in enzyme density suggests an increase in tissue metabolism. Various interpretative hypotheses are included.

- 8808 PRIMARY GASTRIC LYMPHOMA AND ITS GRADES OF MALIGNANCY. (E.) Stobbe, J. (Mayo Clin., Rochester, Minn.), M. B. Dockerty and P. E. Bernatz. Am. J. Surg. 112(1):10-19, 1966.

Of 126 patients treated for primary gastric lymphoma over the last 61 yr. at Mayo Clinic, 108 were treated by partial gastric resection of whom 65% survived more than 5 years. Eighty-one of these 108 patients who had deeply invasive primary gastric lymphoma and who survived the postoperative phase showed a 5-yr. survival rate of 67%. When this group was subdivided according to the grade of malignancy, the 5-yr. survival rate for Grade 1 through 4 was 94%, 81%, 66% and 36%, resp. The 5-yr. survival rate for the 7 patients treated by total gastrectomy was 42.4%, while it was only 9% for those 11 patients whose lesions were too advanced for curative surgery. Only 40-50% of all the patients who had involvement of the lymph nodes survived 5 yr. Rarely did the patient's history strongly suggest gastric lymphoma and the duration of the illness did not correlate with the size of the lesion. The most helpful diagnostic laboratory procedure was the barium-contrast examination of the stomach. Roentgen ray therapy is recommended where the performance of curative surgery is impossible.

- 8809 HISTOLOGY OF THE RAT STOMACH AFTER FREEZING. (E.) Buchan, R. (U. Leeds, England) and C. G. Clark. Brit. J. Surg. 53(5):468-473, 1966.

Coagulation necrosis affecting the whole gastric mucosa resulted after uniform gastric freezing at -10°C for 5 min. in male rats (Hooded Lister strain). Within 2 wk. the entire mucosa had sloughed off. Re-epithelization was delayed for about 2 wk. and then rapidly covered the now contracted glandular area with an epithelium resembling the normal pyloric mucosa. Generally, parietal cells did not repopulate this mucosa (2 of 17 rats showed this phenomena) even when a few were preserved at the squamoglandular junction. In 2 animals where acid secretion was present, recognizable areas of preserved parietal cells were also present. After 14 mo., the gastric capacity remained about half-normal while the mucosa looked macroscopically normal despite the loss of the normal definition between body and pyloric portions. All showed achlorhydria when histamine tests were performed.

- 8810 A NEW DOUBLE-LUMEN GASTROSTOMY TUBE FOR USE AFTER VAGOTOMY. (E.) Burns, G. P. (Postgrad Sch. Med., London, W. 12) and T. Menzies. Brit. J. Surg. 53(5):433-435, 1966.

A double-lumen gastrostomy tube has been designed specifically for use after vagotomy and pyloroplasty (or gastrojejunostomy). The overall length of the tube is 72 cm, the feeding tube being longer than the aspirating gastric tube at both ends. The 20 cm distal extension has six large holes confined to the terminal 5 cm which enables feeding fluids to be delivered well away from the stroma. A narrow strip of plastic-coated linen is incorporated in the tube which makes a transfixing stitch possible and secures the tube to the stomach and the skin. The observation of 50 patients using this tube illustrated the following advantages: the risk of esophagitis and stricture formation as well as a higher incidence of respiratory tract complications reported with the usage of a naso-gastric tube is eliminated; besides less discomfort, early and easy mobilization of the patient is possible; all aspirated gastric juices may be returned to the bowel and protein and calories may be given the first day after operation. A feeding regime is presented.

- 8811 GASTRIC ACIDITY IN THE FIRST DAY OF LIFE. (E.) Avery, G. B. (Child Hosp. Washington, D. C.), J. G. Randolph and T. Weaver. Pediatrics 37(6):1005-1007, 1966.

Two hundred tests of gastric secretion were performed on 65 full-term healthy infants. Within 15 min. after birth their stomachs were intubated and as much gastric fluid as possible withdrawn, volume and pH determined. In 32 babies similar measurements were taken at 4 and 24 hr., or 2 and 3 hr. after delivery. In 12 babies the stomach was washed after the initial contents were removed and a second sample taken 40 min. later. Gastric pH was found to be alkaline immediately after birth shifting rapidly and permanently to acid in 2 hr. Washing was found to render the gastric secretions acid. Cesarean section babies had higher gastric pH. The post-delivery alkalinity was assumed to be due to amniotic fluid. It was recommended that babies' stomachs be emptied after Cesarean section to avoid vomiting and aspiration.

- 812 MODIFIED ENGEL-STEINBERG TECHNIC OF TOTAL, PROXIMAL AND DISTAL GASTRECTOMY. (E.) Minkari, T. (Cerrahpasa Hosp., Istanbul, Turkey). Int. Surg. 46(1): 14-23, 1966.
- Twenty six cases of gastric cancer were operated on; 3 underwent extended proximal gastrectomy using the standard Engel-Steinberg technic; of the remaining 23, 5 were gastrectomized, 5 underwent extended proximal gastrectomy and 13 extended distal gastrectomy. In all 23 cases a modification of the Engel-Steinberg technic was used, i.e. a trousers-shaped food reservoir was constructed by a side-to-side jejuno-jejunal anastomosis which included the duodenal arch into the new digestive passage. A partial ligature was placed over the jejunum which formed the left branch of the neogaster. Follow-up studies (3 mo. to 3 yr.) indicated that 4/5 total gastrectomized, 5/5 proximally gastrectomized and 10/13 distally gastrectomized patients had normal appetite and hunger feelings. Eighteen could eat normally, 5 could eat with effort, 1 suffered an epigastric metastasis. Fifteen patients could return to their old jobs within 6-10 mo., 15/23 patients gained weight, only one (metastasis patient) lost weight. Radiologic studies showed that complete emptying of the neogaster occurred in about 60-80 min. In none of the cases was the dumping syndrome, fermentative diarrhea, glucosuria or small stomach symptoms noted.

SMALL INTESTINE

- 8887 REGENERATION OF THE LYMPHATIC SYSTEM AFTER TRANSPLANTATION OF THE SMALL INTESTINE. (Cz.) Kočandrlé, V. (U. Chicago, Ill.), E. Houttuin and J. Prohaska. Rozhl. Chir. 45(4):261-265, 1966.

In experiments on 28 adult dogs weighing 15-30 kg, autotransplants of the entire small intestine were performed in 14 animals by a modification of the technic of Lilleheim and co-workers, and, by the same technic, allotransplants of the entire small intestine in 14 others. In the autotransplant group, the first signs of lymphatic regeneration were observable with Evans Blue inj. at 2 wk., and at 20 day with roentgen lymphography. Four wk. after autotransplantation, the process of lymphatic regeneration was complete, the macroscopic and microscopic appearance of the transplant being perfectly normal. In the allotransplant group, although the initial postoperative course was the same as after autotransplantation, the immunobiologic reaction set in between day 4 and 8, and no dog survived more than 10 days. (No treatment was given to suppress the immune reaction.) With neither type of lymphography was any evidence seen of the formation of a connection between the transplant and the lymphatic system of the recipient. It would therefore seem that, while the lymphatic system may contribute in some way to the response to allotransplantation, it is not involved in the actual transport of the substances responsible for rejection of the transplant, and that these substances must be carried in the blood.

- 8888 STUDY OF GANGLIONIC CELLS IN THE JEJUNUM IN PATIENTS WITH DUMPING SYNDROME (Sw.) Heijlenskjöld, F. (Gen. Hosp., Malmo, Sweden), S. Hedenstedt and A. G. H. Lindgren. Nord. Med. 75(22):621-622, 1966.

Twenty patients in whom gastric or duodenal ulcer had been treated by gastric resection and creation of an antecolic gastrojejunostomy with a relatively long loop (complemented in a few cases by enteroanastomosis) developed dumping syndromes severe enough to warrant a second intervention after periods of 1-26 yr. Intervention consisted of abolishing the original gastrojejunostomy and simultaneous isolation of a segment of descending jejunal loop which, with its associated mesentery, was then drawn up in such a way that the mesentery could be made a part of the mesocolon retrocolonically while the jejunal segment was anastomosed to form an antiperistaltic interposition between the duodenal stump and the gastric remnant. In all patients, the descending loop from which the interposed segment was derived was severely dilated and varicoid, while the isolated (dilated) segment contracted spontaneously and showed normal peristaltic action after interposition was accomplished. Histologic study of a specimen taken from the loop showed chronic, inflammatory changes in the mucosal layer without any sign of degeneration of ganglion cells.

- 8889 THE SMALL INTESTINE IN SKIN DISEASES. (E.) Fry, L. (London Hosp., E.1), R. M. H. McMinn and S. Shuster. Arch. Derm. (Chicago) 93(6):647-653, 1966. Intestinal biopsies taken from 16 patients with eczema who were selected because of their extensive, chronic condition (often associated with pigmentation) showed that one patient had flat jejunal mucosa with steatorrhea. A six-mo. follow-up showed that the eczema improved while the patient was on a gluten-free diet. Infiltration with eosinophil polymorphonuclear cells was found in the small intestine of patients with atopic eczema or psoriasis (3 patients). Two of the 4 patients with ichthyosis vulgaris and two of the 3 with acrodermatitis enteropathica showed a histochemical decrease of succinic dehydrogenase in the intestinal epithelial cells. One among the 6 patients with Brocq's ichthyosiform erythrodermia had abnormal villi.

- 8890 A TECHNIQUE OF VALVULAR JEJUNOSTOMY IN SHEEP. (E.) Hopcroft, S. C. (Queen Elizabeth Hosp., Woodville, South Australia). Exp. Med. Surg. 24(1):97-103, 1966.

A technic of valvular jejunostomy in the sheep is described which allows the sampling of succus entericus in different phases of intestinal activity or under different pharmacological influences. Neither a mortality nor morbidity resulted from this operation when it was performed consecutively on 20 sheep. No fistulas developed.

The intestine is partially transected at the desired site of intestinal anastomosis and the proximal segment is approximated to the area of transection and anastomosed with a T-piece with the distal segment of the gut. Afterwards, the access loop and distal segment are united to form an inverted Y. In this way the succus entericus being propelled by peristalsis down the gut reaches the access loop as well as the distal segment. A modified Foley catheter is used for collection.

891 JEJUNOILEAL ATRESIA AND STENOSIS. (E.) Louw, J. H. (U. Cape Town, South Africa). J. Pediat. Surg. 1(1):8-23, 1966.

Retreatment of 33 consecutive cases of jejunoileal atresia and stenosis by resection and primary anastomosis gave an overall survival rate of 91%. In the last 10 of these cases where end-to-end anastomosis (rather than side-to-side) was used, the survival rate was 96%. Resection of up to 30 cm of bowel was tolerated without nutritional problems. Experiments using dogs showed conclusively that infarction of a segment of fetal intestine may result in a progression of jejunoileal (and colonic) anomalies varying from widely separated blind ends to intestinal stenosis. Furthermore, clinicopathologic study of 85 cases with jejunoileal lesions revealed that many of the deaths were due to technical failures and that the principal factor responsible for the failures was impaired viability and contractility of the ileal end of the proximal intestine. This appeared to be due to deficient blood supply. Delay in diagnosis, inadequate supportive care and prematurity and associated abnormalities (principally meconium peritonitis and omphalocele) were other factors reviewed which contributed to the previously reported higher mortality rate.

892 INTRACELLULAR ELECTROLYTE PATTERN DURING EXPERIMENTAL INTESTINAL OBSTRUCTION. (Ger.) Staib, I. (U. Marburg, Germany). Bull. Soc. Int. Chir. 25(2):93-100, 1966.

Measurements at regular intervals were performed on arterial, venous and urinary specimens and on biopsy specimens from muscle, liver, and various intestinal portions, on 12 dogs with experimentally induced strangulation ileus and 15 dogs with experimental occlusion ileus. The animals were maintained after surgery on 25 ml/kg 5% levulose with 50-60 mEq NaCl and 20-30 mEq K-lactate replacement of withdrawn blood, plus a plasma expander, and up to 1 million U penicillin and 0.5-1.0 g streptomycin. Extracellular space determined with Na-thiosulphate (S-35) remained constant throughout (20% scatter with 3.5% standard deviation), together with total tissue water from muscle, liver, jejunum and ileum (scatter to: 3% and 3-11%, resp., for healthy or gangrenous intestinal tissue). Serum Na, K, Ca, and Cl remained unchanged; only inorganic phosphate became elevated 24 hr. after strangulation ileus. An identical pattern was found in RBC. No K change, but a significant Na increase, occurred in muscle in occlusive ileus. In the liver, K values were significantly lower in the strangulated group compared with the occlusion group. In the latter group, Na showed only minimal decrease. No changes in intestinal tissue were seen; Na loss (Na gain) appeared only with visible tissue damage. The membrane potentials were similarly altered, which dropped only before death (in liver and gangrenous intestines) to 85 mV. The electrolyte balance (total body) showed Na retention without K loss, and the acid-base balance (plasma and RBC pH, CO₂ and bicarbonate) remained essentially unchanged except for a terminal metabolic acidosis. It is felt that the intracellular space is a multicompartiment unit and that determinations of electrolyte balance alone do not reflect electrolyte changes in various organs; the value of analyzing biopsy specimens is stressed.

893 AN OBJECTIVE METHOD OF DETERMINING INTESTINAL VITALITY IN ILEUS. (Rus.) Ivanov, V. V. (Chuvash Region Hosp., USSR). Vestn. Khir. Grekov. 96(4):48-50, 1966.

A study of intestinal vitality was made in 38 animals (dogs, cats, and guinea pigs) and in 21 patients with acute intestinal obstruction and strangulated hernia. In the first series (16 animals with normal intestine), the i.m. or s.c. admin. of acetylcholine (1; 0.5-1.0 ml in 1:10 dilution) caused intestinal peristalsis lasting 5-10 min. in most cases, while the admin. of 0.2-0.3 ml in 1:10⁴ and 1:10¹⁰ dilutions directly into the mesentery of the small intestine caused (in less than 1 second)

violent, undulating, contractions of the corresponding intestine segment lasting an av. of 2-3 min. This violent peristalsis was accompanied by marked dilation of the branches of the mesenteric artery and stimulation of their pulsations. Other cholinergic drugs had no such effect. In the second series, the admin. of I (0.5 ml in 1:10¹⁰ dilutions) into the lumen of isolated intestine in normal dogs with a Thiry-Vella loop caused immediate, energetic, intestinal contractions and ample secretion lasting 3-5 min. In the third series, after elimination of intestinal obstruction induced by artificial strangulation of an intestinal loop with mesentery for 2-5 hr. or more, the admin. of I into the mesentery caused peristalsis in the affected intestine only if strangulation did not exceed 3-4 hr. In the portion of the affected intestine which responded to I, pathological changes induced by strangulation were reversible; in the portion which failed to respond to I, lesions were not reversible. In the fourth series, the admin. of I (0.2-0.3 ml in 1:10⁴ dilutions) into the small intestine lumen of cats (12) stimulated the tonus and provoked marked intestinal peristalsis. Stimulation and increased duration of motor effects were observed following the admin. of I and proserine (0.3-0.01%); motor function was stimulated following I and novocaine splanchnic nerve block. Unusually violent contractions of the whole intestine (not inhibited by atropine) occurred after vagus stimulation by I (1 ml in 1:10⁴ dilution). Using the author's method, I and other cholinergic agents were used successfully in 2 patients to determine the vitality of the impaired intestine.

- 8894 THE EFFECT OF NECROSIS AND TUMOR ON THE CELL KINETICS OF SMALL BOWEL. (E) Betts, A. (Maine Med. Ctr., Portland), E. L. Sewall and R. Tanguay. Cancer Res. 26(5):898-902, 1966.
Adult hamsters (114) received 75 μ C each of thymidine-³H i.p. The animals were killed at intervals up to 24 hr., a segment of small intestine removed, fixed and 3 μ paraffin sections cut. Autoradiographic slides were prepared, stained and examined for mitotic figures in the crypt area of each segment of jejunal epithelium. Percentage labeled cells (having 10+ autoradiographic dots) were determined for 50 mitoses. Thirty animals were controls, 31 were prepared with turpentine-induced thigh necrotic abscesses and 30 had a fibrosarcoma transplanted to the scapular region. Twenty-three additional animals were used to evaluate the accuracy of the counts. To establish S-phase and generation times the time necessary to produce 50% labeling of mitotic figures was noted. When the longest possible normal DNA synthesis time and generation time were compared with the shortest times for the experimental groups the S-phase time and generation time of the experimental group were 3 hr. shorter. When the shortest normal times were compared with the longest times of the experimental groups the S-phase times of the experimental groups were 1.5-2 hr. longer but the generation times were similar. It is suggested that both inflammatory lesions and tumors cause acceleration of cell turnover in other regenerating tissues and that this increase may contribute to the cachectic state.

Peptic Ulcer

- 8942 EXPERIMENTAL STUDIES ON THE RELATIONSHIP OF HEPATIC CIRRHOSIS AND PEPTIC ULCERATION. (E.) Singh, G. B. (Inst. Cent. Drug. Res., Lucknow, India) and S. H. Zaidi. Indian J. Path. Bact. 8(3): 178-183, 1965.

Peptic ulceration produced by pyloric ligation was more severe in male albino rats with induced cirrhosis (Group 4: admin. CCl₄ s.c., 0.2 ml/100 g; twice weekly for 8 wk.) than in noncirrhotic animals (Group 3). In Group 4, all the rats developed multiple ruminal ulcers ranging 4-7 mm in diameter of which 2 were perforated, whereas in Group 3, there was no perforation and the diameters ranged from 1-3 mm. A significant difference was also seen in the peptic activity (greater in 4) and the amount of mucin (almost twice as much in 3) in the gastric juice. However, the gastric juice volumes were similar. In Group 2 (where only cirrhosis was induced) the stomach only showed signs of chronic inflammation.

- 8943 PRIMARY HYPERPARATHYROIDISM AND PEPTIC ULCER. (Cz.) Pacovsky, V. (Charles U., Prague, Czech.), J. Hrba and V. Jirasek. Cas. Lek. Cesk. 105(15): 399-402, 1966.

Among 61 patients with primary hyperparathyroidism (I), 15 (24.5%) had a peptic ulcer of the stomach, duodenum, or jejunum (demonstrated by X-ray, surgery, or autopsy). Anamnesis revealed ulcer symptomatology in 27 patients (44.2%). The pylorus and pre-pyloric part of the stomach were involved most frequently. Serious complications (perforations, hemorrhage, stenosis) occurred in 10 of 15 (75%) with proven ulcer. Positive family history of peptic ulcer was obtained in 9 of 15 (60%) with proven ulcer, in 7 of 12 (58.3%) with ulcer symptomatology, and in only 12 of 34 (35.3%) without ulcer symptomatology. In all patients with chronic ulcer, it occurred 2-7 yr. prior to the diagnosis of I. After elimination of the hyperfunction of the parathyroid glands, the ulcer symptomatology regressed in 11 of 15.

- 8944 PHYSIOPATHOLOGICAL AND CLINICAL CONSIDERATIONS ON THE ALTERATION OF GASTRIC SECRETION AND MOTILITY AND THE APPEARANCE OF GASTRIC ULCER DURING CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (Rum.) Giorapciu, S., M. Andronescu and C. Ionita. Med. Intern. (Bucur.) 18(4):437-448, 1966.

Analysis of 150 cases which included 93 patients with chronic hepatitis of various degrees of severity, 39 patients with liver cirrhosis, and 18 patients with liver pathology of diverse etiology associated with gastric or duodenal ulcer, showed that gastric secretion and motility decrease in direct proportion with the progress of disease; gastric hypotony and hypokinesis become more pronounced as the disease approaches the stage of cirrhosis. This development is independent of the etiology of the hepatic condition. The pathogenesis of this phenomenon is quite complex, due partly to poor irrigation of the gastric mucosa (a direct result of existing portal hypertension), and partly to endocrine disturbances, enterocolic processes, etc., they may occur in alcoholism or other types of parenchymal damage. Appearance of an ulcerative condition results in an increase of gastric acidity (both qualitatively and quantitatively) and gastric motility. It is suggested that such an increase of the usually depressed values found in chronic hepatitis may indicate incipient ulcer formation, and that special attention should be given to therapy aimed at normalizing such values; close follow-up studies are suggested, especially during prolonged treatment with corticosteroids.

- 8945 GASTRIC SECRETION AND ULCER FORMATION AFTER HYPOPHYSECTOMY AND ADMINISTRATION OF SOMATOTROPHIC HORMONE. (E.) Robert, A. (Upjohn Co., Kalamazoo, Mich.), J. P. Phillips and J. E. Nezamis. Am. J. Dig. Dis. 11(7):546-552, 1966.

Transauricular hypophysectomy in female Sprague-Dawley rats (wt. 180-200 g) reduced the volume of gastric secretion and also the conc. of acid, mucus, and pepsin to very low levels. Five days after hypophysectomy, s. c. inj. of bovine somatotrophic hormone (I) restored nearly completely the acid, partly the volume and the mucus, but failed to increase the pepsin. Pepsin secretion, at least in the rat, appears to be regulated by pituitary-dependent glands rather than directly by I. Hypophysectomy reduced ulcers induced by prednisolone (0.5 mg/day s.c. for 2 days) by 45%; the

decrease affected incidence, severity, and number of ulcers per stomach and was even more marked (81%) when the animals were also given I. The protective effect of hypophysectomy is not explained. The anti ulcer effect of I may be due to protection afforded by increased mucus, despite increased acid secretion. It may also be due to increased stimulation of gastric connective tissue.

946 THE AETIOLOGY OF BENIGN LESSER CURVE GASTRIC ULCER: VAGOTOMY AND PYLOROPLASTY IN ITS TREATMENT. (E.) Burge, H. (West London Hosp.). Ann. Roy. Coll. Surg. Eng. 38(6):349-369, 1966.

Evidence is presented which indicates that lesser curve gastric ulcers are caused by gastric retention, persistent or transient, from pyloric or duodenal disease. Vagotomy and pyloroplasty is cited as the choice treatment, while gastric resection is strongly disfavored. Examination of almost every specimen in the museums of the London teaching hospitals in which the pylorus was intact and a benign lesser curve ulcer was present showed evidence of pyloric channel disease or duodenal ulceration. In current studies of benign lesser curve gastric ulcers, duodenal or pyloric channel disease was present in almost every case. Extremely favorable results are presented in 72 cases of uncomplicated lesser curve gastric ulcer after treatment by vagotomy and pyloroplasty.

947 CLINICAL PATHOLOGY OF GASTRIC ULCER. (Pol.) Oszacki, J. (2nd Dept. Surg., Acad. Med., Cracow, Poland), A. Urban, K. Szczgiet and J. Kulpa. Pol. Przegl. Chir. 38(4):265-272, 1966.

Partial gastrectomy was carried out in 234 patients (av. age 50.5 yr.) with 278 gastric ulcers (77 women; 157 men, 67%; multiple ulcers in 37 of 234). It seems that women have a tendency for ulcers of the corpus of the stomach, whereas this location is very rare in men. Blood group "O" predominated among the cases with ulcers of the corpus of the stomach whereas the cases with ulcers of the pyloric region generally possessed the blood group "A". However, the total number of patients was not sufficient to make generalizations in this respect. The av. age of women and men was very close (50.5 and 50.6 yr., resp.). The ulcer size did not correlate with its location.

948 EMOTIONAL RESPONSES TO PEPTIC ULCER MANAGEMENT. (E.) Ely, N. E. (U. Washington Sch. Med., Seattle) and M. H. Johnson. Am. J. Psychiat. 122(12):1362-1371, 1966.

The group of peptic ulcer patients was followed for 1-3 yr. in the absence of surgical intervention; another was followed for 1-4 yr. postgastrectomy. In both groups, annual reevaluations included a psychiatric interview, the Cornell Medical Index questionnaire and the Minnesota Multiphasic Personality Inventory questionnaire. Among 15 nonoperated patients, only 3 experienced relief of ulcer symptoms, symptoms became severe in 3, symptoms continued to be moderate to mild in the rest. The questionnaires and psychiatric interviews indicated that this group of patients also tended to remain emotionally stabilized in terms of pretreatment personality patterns. There were no recurrent ulcer symptoms among 15 gastrectomized patients, but 13 (as contrasted to 3 in the medically treated group) developed a wide range of new symptoms, including chest, back, neck and/or abdominal pain, fatigability, objectively confirmed hypertension, insomnia, "nervousness," wt. loss, diarrhea and dizzy spells. Following an initial decrease, immediately after surgery, the frequency and severity of gastrointestinal complaints tended to return to the preoperative level fairly promptly, while complaints of a psychoneurotic or psychophysiologic nature tended to increase progressively for the group as a whole. Some of the individual profiles derived from the questionnaires showed greater changes than were seen in any of the profiles of the nonoperated group, both in the direction of increased psychopathology and in the direction of decreased psychopathology. It is concluded that surgical treatment of the ulcer, without simultaneous treatment of underlying anxieties and conflicts, tended to result in the development of new symptoms, which replaced the original ulcer symptoms' role as a means of maintaining psychodynamic homeostasis.

949 COMPARISON OF POSTGASTRECTOMY COMPLICATIONS IN GASTRIC AND DUODENAL ULCER PATIENTS. (E.) Magnuson, F. K. (Mayo Clin., Rochester, Minn.), E. S. Judd and W. H. Dearing. Am. Surg. 32(6):375-382, 1966.

A comparative study of postoperative complications after subtotal gastrectomy (generally 66-75%) with either a Billroth I or Billroth II reconstruction was conducted on 230 duodenal ulcer patients and 95 gastric ulcer patients. The surgery was conducted over a one-yr. period during which there was only one hospital death. In the gastric ulcer group 2 subsequent deaths were related to the resection and 8 other deaths were due to other conditions, as were the 21 deaths (over a 7-yr. period) in the duodenal group. Most of the patients were between 30 and 69 yr. of age. Leakage of the duodenal stump was the most common complication in the combined groups as well as in the duodenal group, occurring most often after Billroth II operations. Vomiting and diarrhea were the most frequent complications in the gastric group. More than 50% of the duodenal ulcer patients and 39% of the gastric ulcer group showed a weight loss, while postgastrectomy anemia occurred in 5.7% and 6.8%, resp. The dumping syndrome occurred in 31.6% of the gastric ulcer group and 40.4% of the duodenal ulcer group; females were afflicted almost twice as often as males and these patients were more prone to recurrent ulceration. In general, gastric ulcer resections had fewer and less severe postoperative complications than duodenal ones.

- 8950 HISTOCHEMICAL STUDIES OF MUCOPOLYSACCHARIDES OF THE GASTRIC MUCOSA AT THE SITE OF PEPTIC ULCER. (It.) Petrelli, A. E. (U. Modena, Italy). *Riv. Gastroent.* 17(5):272-284, 1965.

Histochemical studies were conducted on gastric mucosa specimens obtained from 15 patients of both sexes (age 34-52 yr.) following partial gastrectomy for peptic ulcer of the antropylic region. The presence of mucopolysaccharides was determined by the Hotchkiss-McManus reaction, the Alcian Blue 8 GS and 8 GN, and a combination of the 2 methods. Twelve patients showed evidence of metaplasia characterized by the appearance of goblet cells with large cytoplasmic vacuoles, especially in cases with deeper and more severe ulcerations. The Hotchkiss reaction was markedly positive in the mucosa near the ulcer and in areas of the epithelium and stroma which showed reproductive activity; positive-staining material was found in the goblet cells, while that of the stroma was only slightly positive or negative; in areas further from the ulcer, the reaction was limited to the superficial margin of the epithelial layer of the glandular portion. The Alcian reaction was similar to the Hotchkiss, except that the latter prevailed in the middle portion of the stomach. Similar variability of results was observed using the combined reaction. Results indicate an increase in phosphomonoesterase activity in relation to an increase in mucopolysaccharides in the gastric mucosa in proximity to the ulcer. The behavior of the reaction depends upon the presence of acid groups in the Alcian and of 1,2-glycol groups in the Hotchkiss.

- 8951 EXPERIMENTAL CHRONIC GASTRIC ULCER IN THE RAT. II. EPITHELIAL CHANGES IN THE MARGIN OF THE ULCER. (E.) Lauren, P. (U. Turku, Finland) and B. Holmberg. *Ann. Med. Exp. Fenn.* 44(1):44-48, 1966.

Atypical epithelium interpreted as precancerous in the margins of chronic ulcers induced by irritation with a methylcholanthrene-impregnated sponge in the glandular stomachs of 27 rats was studied by histochemical methods. The superficial epithelium secreted profusely and contained occasional cells similar in form to the goblet cells of the intestinal epithelium. With methods used to demonstrate acid mucus (mucicarmine, aldehyde fuchsin, and Hale techniques), the stainability varied from nearly negative to an intense reaction given by the cells resembling goblet cells; Best's carmine was faint or negative. Staining reactions in normal rat gastric mucosa were similar, however. Invasive glandular proliferation corresponded to pyloric glands structurally, but had scanty secretion, and in the most peripheral and most atypical parts the staining of the mucus differed from that of all types of mucus in normal stomach and intestine in that it was negative to aldehyde fuchsin. Both normal and atypical gastric mucosa gave the same results in enzyme studies performed on 16 stomachs: alkaline phosphatase and leucine aminopeptidase were negative, adenosine triphosphatase and 5-nucleotidase were positive. Since no characteristics of intestinal mucosa other than cells resembling goblet cells were seen, and the tissue enzymes retained their gastric character, the authors do not regard the changes as corresponding to intestinal metaplasia in man and suggest

t the lack of a tendency to form intestinal metaplasia may be one reason for the difficulty of inducing carcinoma in the rat glandular stomach.

- 2 EXPERIMENTAL CHRONIC GASTRIC ULCER IN THE RAT. 1. INDUCTION OF THE ULCER USING INTRALUMINAL APPLICATION OF METHYLCHOLANTHRENE IN POLYVINYL SPONGE. (E.) Lauren, P. (U. Turku, Finland) and B. Holmberg. Ann. Med. Exp. Fenn. 44(1):40-43, 1966.

manent chronic gastric ulcers developed in white rats within 370 days following intraluminal application of a polyvinyl sponge ball (2 mm diameter) impregnated with methylcholanthrene mixed with paraffin or polyethyleneglycol. The ball was placed against the mucosa via an opening cut in the forestomach, and held in place by winding silk thread around the outside of the stomach at the site of the bulge, producing a non-occluded loose pouch. In the methylcholanthrene-paraffin group, 13 of 15 showed chronic ulcers; ulcer scars were seen in 2 rats, and 6 showed an inflammatory condition. In the methylcholanthrene-polyethyleneglycol group, 15 showed chronic ulcers, 2 ulcer scars, and 4 inflammatory changes. The chronic ulcers extended through the muscularis propria, with profuse granulation tissue in the floor of the ulcer. The cell density of the granulation tissue was high and reminiscent of fibrosarcoma, although there was no demonstrable sarcomatous tissue. Atypical glandular tissue was seen in the ulcer margin in all cases continuing into the granulation and connective tissue. The glands displayed disorganized grouping and were often cyst-like of variable morphology. There was no definite limit of spread and growth appeared to be invasive. Spread to the lymphatics or metastasis to other organs was not demonstrable.

- 3 DUODENAL ULCER IN INFANTS. (E.) Gieske, J. P. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and B. Storey. Bull. Hopkins Hosp. 118(6):499-506, 1966.

A review of 2 infants (7 mo. and 5 mo. old) with chronic primary duodenal ulcer is presented. A review of 42 other proven cases of peptic ulcer (15 primary and 27 secondary) in children (birth to 14 yr.) seen during an 8-yr. period is presented. The total primary group of 17 patients (10 male, 7 female) had 2 gastric and 15 duodenal ulcers; 5 patients were under 1 yr. of age at the time of diagnosis, 4 were 1-4 yr., and 8 were 5-14 yr. old. Pain was the predominant symptom in the older children, whereas vomiting and signs and symptoms of blood loss were predominant in the younger. Three patients required surgery, 2 for perforation and 1 for intractability. The group with secondary ulcers consisted of 10 male and 17 female patients with 15 gastric and 16 duodenal ulcers (4 patients had both); there were 10 patients under the age of 1 yr., 12 from 1 to 8 yr., and 5 from 9 to 14 yr. Congenital heart disease (6 patients) was the most common primary disease present. Because 19 of 22 secondary ulcers were not diagnosed before autopsy, the authors suggest a need for increased awareness of ulcer disease in the ill child.

- 4 VAGOTOMY AND PYLOROPLASTY. AN INADEQUATE OPERATION FOR STRESS ULCER. (E.) Bryant, L. R. (U. Kentucky Med. Ctr., Lexington) and W. O. Griffin, Jr. Arch. Surg. (Chicago) 93(1):161-170, 1966.

There were multiple stress ulcerations occurring in 5 individuals. The precipitating causes were central nervous system injury in 4 and acute heart failure in 1. Massive upper gastrointestinal hemorrhage also occurred. Suture ligation of the bleeding vessel with vagotomy and pyloroplasty was done in 4 patients; excision of the bleeding gastric ulcer was the initial procedure in 1. All patients rebelled within 7 days. One patient died of exsanguination; 4 required secondary gastric resection to control bleeding. The stress ulcerations were multiple in all 5 patients; this partly explains the failure of pyloroplasty with vagotomy and suture ligation to prevent rebleeding. Although partial gastrectomy with vagotomy is a procedure of greater magnitude, it is recommended as the initial operation when treating hemorrhage associated with stress ulcerations.

- 5 PERFORATION OF GASTRO-DUODENAL ULCER IN THE TUNISIAN POPULATION. THE EFFECT OF RAMADAN ON THE FREQUENCY OF PERFORATIONS. (Cz.) Vach, B. (Charles U., Prague, Czech.). Rozhl. Chir. 45(5):300-304, 1966.

SMALL INTESTINE

Peptic U

Over a 3-yr.-period, 195 Tunisians were treated for perforated gastroduodenal ulcer. In 86%, the ulcer was in the pyloric region. Analysis of the comparative frequency of perforation in each month of the year revealed that 3.5x as many perforations occurred during the month of Ramadan, when Mohammedans are required to observe a strict fast from dawn to sunset. Since Ramadan shifts from one season to another in accordance with the Mohammedan calendar, it was obvious that the fasting, rather than the season, was responsible for this increased frequency. Factors incident on fasting cited as contributing to perforation are weight loss, the local action of the gastric juice on an empty stomach, and the heightened reactivity of the CNS which is observable after a period of fasting, and especially toward the end of Ramadan. Moreover, perforations were most apt to occur around 11 A.M. and 5 P.M. (1 hr. before the evening meal). The largest number of perforations occurred in subjects aged 30-39 yr. (35.2%), the next largest in those aged 40-49 yr. (25.5%) and 20-29 yr. (20.9%), that is, at an earlier age than in Europe, where successful conservative treatment shifts the max. frequency of perforation to decade 5. In Tunisia, most ulcer patients go untreated until perforation creates an emergency. In the author's cases, despite the necessity of operating unassisted and with only one nurse, all 195 patients survived surgery, which was limited (owing to the above conditions) to suturing only in 98.2% of the cases. All wounds healed by first intention.

- 8956 HYPOKALAEMIA, FLACCID QUADRUPARESIS, AND MYOGLOBINURIA WITH CARBENOXOLONE (BIOGASTRONE). (E.) Mohamed, S. D. (U. Aberdeen, Scotland), R. S. Chapman and J. Crooks. *Brit. Med. J.* 1(5503):1581-1582, 1966.

A 58-yr.-old woman being treated with carbenoxolone (100 mg three times a day) for a chronic gastric ulcer developed marked hypokalemia (serum K 1.8 mEq/liter), myoglobinuria, and extensive flaccid paresis with focal necrosis of muscle by biopsy. There was no weight gain or elevation of blood pressure. Symptoms began on day 38 of carbenoxolone treatment and became marked over the next 48 hr. Complete recovery ensued after withdrawal of the drug (day 39) and correction of the K deficit; the myoglobinuria disappeared in 3 days, serum K levels were normal in 10 days, and the patient was symptom-free in 2 weeks.

- 8957 ALIMENTARY CHYLOMICRONEMIA IN PEPTIC ULCER AND AFTER PARTIAL GASTRECTOMY (Pol.) Jezioro, Z., S. Piegza and W. Soltys. (*Pol. Arch. Med. Wewnet*) 36(1):43-49, 1966.

Nutritional chylomicronemia was determined by means of measuring the optical density of serum in 20 normal subjects, in 24 patients with peptic ulcer, in 15 patients with partial gastrectomy by Tydygier's method, and in 15 patients with partial gastrectomy by the Polya-Reichel method. In comparison with normal subjects, the values of chylomicronemia in 25% of cases with peptic ulcer showed a flatter curve; however, this was ascribed to disturbances in the emptying of the stomach since partial gastrectomy was followed by normalization of the chylomicrogram. After partial gastrectomy the duration of chylomicronemia was shortened and its top values were at normal levels. After resection by the Polya-Reichel method, a flattening of the curve of chylomicronemia was noted in 6 of 15 cases. This finding seems to indicate that with this type of resection, gastric function is almost critically impaired, and the exclusion of the duodenal passage is not always compensated for. Partial gastrectomy does not seem to impair the mechanism of fat absorption.

- 8958 ANTI-ULCER ACTION OF SOME ESTERS OF FARNESYL ACETIC ACID ON THE GASTRIC MUCOSA OF GUINEA PIGS AND RATS. (Cz.) Šmejkal, V. (Inst. Pharm. Biochem. Prague, Czech.), A. Dlabac and V. Trcka. *Cesk. Gastroent. Vyz.* 20(3):154-157, 1966.

Damage of gastric mucosa was induced in guinea pigs (males, wt. 250-400 g) with histamine (50 mg/kg i.m. every 8 hr.). Ten min. before histamine admin., pyribenzamine (10 mg/kg i.m.) was given. The agent to be tested was injected or given by sound 2 hr. before the admin. of histamine. Gastric mucosa damage was induced in male Wistar rats (wt. 130-200 g) by s.c. admin. of phenylbutazone, 100 mg/kg/day 3 times. The animals were sacrificed on the 4th day. An ester of farnesyl acetic

DUODENAL INTESTINE

was admin. p.o. (by second) simultaneously with the phenylbutazone. The incidence of ulcers in guinea pigs with methyl ester (100 mg/kg s.c.) was 85% in 20 controls and 84% in 19 experimental animals; with phytyl ester (100 mg/kg s.c.), 88% in controls, and 71% in 17 experimentals; with butyl ester (100 mg/kg s.c.), 85% in controls and 59% in 17 experimentals (statistically significant). In rats, the incidence of ulcers was 100% in 18 controls; with butyl ester (50 mg/kg p.o.), 45% in 9 experimentals; with butyl ester (100 mg/kg p.o.), 50% of 10 experimentals. It is concluded that the butyl ester of farnesyl acetic acid may have a protective effect against gastroduodenal ulcers.

PROPANTHELENE AS AN AGENT FOR MEDICAL VAGOTOMY. (E.) Checketts, R. G. (Royal Infirm., Sheffield, England), I. E. Gillespie and A. W. Kay. Gut 7(2):200-202, 1966.

Twenty-five male patients with proven duodenal ulcers were studied. In 5, Propantheline (30 mg i.v.) inhibited the secretory response produced by insulin (20 units i.v.). In 20 patients the same dose of Propantheline (30 mg i.v.) was admin. with histamine (0.04 mg/kg i.m.) together with Anthisan (50 mg) preceding collection of gastric secretions. All patients received subdiaphragmatic vagotomies; postoperatively an insulin test for completeness of vagotomy was performed followed the next day by collection of histamine (0.04 mg/kg i.m.) with Anthisan (50 mg) stimulated gastric secretion. The data collected was found to be represented by the following formula: $y = .643 + .223x_1 + .168x_2$ where y = postoperative histamine response, x_1 = pre-operative histamine response, x_2 = post-Propantheline histamine response. It is suggested that the formula might be useful in detecting patients in whom vagotomy will not cause a large reduction in gastric acid secretion.

MUSCULAR PAIN DURING THERAPY WITH CARBENOXOLONE (BIOGASTRONE). (E.) Morgan, T. N. (Aberdeen Royal Infirm., Scotland), I. Donald and G. M. McAndrew. Brit. Med. J. 2(5504):48, 1966.

Rapid and sustained remission of disabling, extensive muscular pain followed withdrawal of carbenoxolone treatment. Carbenoxolone (100 mg 3 times/day) plus sodium sulfates and an ulcer diet had been prescribed to a 43-yr.-old male who had a duodenal and a large lesser-curvature gastric ulcer. Six wk. later, stiffness and cramp-like pains developed in the left side of the neck and the left upper arm, then extended later to the left thigh and calf. Within 2 wk., the same condition existed on the right side. On examination, the muscle was tender but there was no obvious induration. There were no signs of peripheral neuritis and no change in the urine color. Two days after the drug was stopped the pain began to subside. Electromyograms taken 2 wk. later were suggestive of myositis.

MUCOSAL ANTRECTOMY IN THE TREATMENT OF PEPTIC ULCER. (E.) Kirk, R. M. (Hampstead Gen. Hosp., London). Proc. Roy. Soc. Med. 59(6):571-575, 1966.

Mucosal antrectomy was successfully performed (longest follow-up 2 yr.) on 44 patients. This technic, removing only the mucous membrane, relies on the inj. of large quantities of epinephrine in saline into the submucosa to separate mucosa from muscularis and to reduce bleeding. The incision starts on the anterior wall of the duodenum and continues on the anterior wall of the stomach midway between the lesser and greater curves. The mucosa is incised at the pyloric ring and stripped off proximally as a sheet for 9-10 cm and excised. The mucosal edges opposed, suturing is started at the center of the posterior wall, the incision in the duodenum can be lengthened to accommodate the width of the stomach. A gastric ulcer can be included in the removal of a flap of mucosa by the same technic up to including the ulcer margins. Max. histamine tests (100 mg mepyramine i.m. followed by 0.04 mg/kg histamine) were carried out in 6 patients. In all cases basal and post-histamine secretion determined by gastric aspiration were greatly decreased from preoperative levels. The operation was recommended because: 1) technically simple; 2) effective; 3) duodenum not closed; 4) gastroduodenum continuity maintained; 5) no major arteries ligated; 6) external suture line is small.

THE FREQUENCY OF CHRONIC GASTRITIS AND DUODENAL ULCER IN PATIENTS WITH RHEUMATIC CARDIAC LESIONS. (Fr.) Iantchev, V. (Inst. Special. Perfect.

Med., Sofia, Bulgaria), E. Iordanov and I. Kountchev. Sem. Hop. Paris 42(28):25-30, 1966.

Among a large group of patients with cardiac lesions secondary to rheumatic disorders, 12 of 1242 also suffered from chronic gastritis; 29 of 1242 had duodenal ulcers. As compared to the incidence encountered in the general population, these frequencies were statistically non-significant. It is concluded that gastric distress resulting from medication with aspirin and other antirheumatics tends to be temporary and to disappear when the irritating medication is withdrawn.

Regional Enteritis

- 8988 LONG-TERM OBSERVATIONS OF PATIENTS WITH CROHN'S DISEASE. (Ger.) Ellegast, H. (U. Vienna, Austria). Radiol. Austria 16(2):111-125, 1966. Among 11 histologically verified cases of Crohn's disease, 10 were localized in the terminal ileal loop (4 of 10, with additional localizations), 1 was limited to the jejunum. One recurrence was seen in 2 of 11, 2 and 8 yr., resp., after initial surgery; 2 recurrences were seen in 1 of 11, at intervals of 1 and 2 yr., resp., after initial surgery; 3 recurrences were seen in 1 of 11, at intervals of 20, 23 and 25 yr., resp., after initial surgery. A 5th patient had a possible recurrence 36 yr. after ileal resection and ileotransversostomy. At the time of report, 2 of 11 had been followed for 31 and 36 yr., resp.; 2 of 11, for 18 and 20 yr., resp. 2 of 11 for 9 and 10 yr., resp.; 5 of 11, for periods of 2 mo.-8 yr. In 5 of 11, the first surgical intervention was made 5-16 yr. after the onset of symptoms; in 4 of 11, 6 mo. to 4 yr. after the onset of symptoms; in 2 of 11, at the time of initial consultation during an acute stage of the disorder. Brief case summaries are included for all of these patients. Also reported are 2 cases of regional colitis and 4 of terminal ileitis, suspected to be possible precursors of the disorder.

Malabsorption

- 02 EFFECT OF THE GERMFREE STATE ON VARIOUS NITROGEN COMPOUNDS IN THE CECUM OF ALBINO RATS RECEIVING VARYING QUANTITIES OF PROTEIN. (Fr.) Combe, E. (Nat. Inst. Agr. Res., Jouy-en-Josas, Yvelines, France) and E. Sacquet. C. R. Acad. Sci. (Paris) 262(6)(Ser. D):685-688, 1966.

axenic rats, the total nitrogen content of the cecum exceeded that of normal controls by 2.5-4.0 times, due in large part to the fact that the cecum accounted 8.5% of the total body wt., versus 1.3% in controls. The conc. of free amino acids was 10-30 times greater in the axenic animals; relative proportions of serine and threonine were 2-4 times greater and those of alanine were approx. one half as great as in controls. Also significantly increased in the axenic animals were cecal conc. of mucoproteins, peptides and urea. Cecal conc. of sodium were essentially the same as those seen in controls, although the potassium conc. was only one fifth control levels.

- 03 CLINICAL SYMPTOMS OF GLUTEN-INDUCED ENTEROPATHY. (Ger.) Fahländer, H. (U. Basel, Switzerland) and M. Seigel. Gastroenterologia (Basel) 105(5):283-293, 1966.

Among 16 patients with gluten-induced enteropathy (confirmed by biopsy and response to a gluten-free diet), 5 showed normal intestinal passage times; 4 had severe constipation; 5 had diarrhea; 10 showed hypocalcemia (3 of 10 with tetany, 4 of 10 with vitamin D deficiency); 6 had hypochromia and none had hyperchrome anemia; 8 suffered from hypoproteinemia and 4 (each) suffered from osteomalacia, hypokalemia and disturbances of blood clotting. Among patients tested, the xylose test was normal in 5 of 14, Schilling's test in 2 of 8 and lipid balance in 1 of 10. It is concluded that the classical picture of sprue is seen comparatively rarely and that indications of pathological malabsorption may be limited to a single symptom or only a few of the conventionally recognized symptoms.

- 04 CELIAC DISEASE IN ELDERLY PATIENTS. REPORT OF 13 CASES, WITH A NOTE CONCERNING DRUG ABSORPTION. (E.) Collins, J. R. (Harvard Med. Sch., Boston, Mass.). Am. J. Dig. Dis. 11(7):564-571, 1966.

Clinical characteristics of 13 elderly celiac patients, 6 male and 7 female, are reviewed in attempt to determine reasons for the delayed onset of symptoms. The disease became symptomatic after age 60 in 10 patients, and was diagnosed for the first time in each of the 13 after age 60. Steatorrhea was evident in every case. Jejunal biopsies, showing marked blunting or absence of villi, were done on 7 patients. Significant improvement was noted by 7 patients on a strict gluten-free diet; 5 showed improvement from mild to marked on cortisone and 1 improved on prednisone. For the 4 patients, who had neither a biopsy nor dietary gluten restriction, celiac disease was suspected because of a typical clinical picture, including a favorable response to corticoids and a careful follow-up of more than 1 yr. Clinical manifestations in these patients resembled those in younger individuals with celiac disease. The late onset suggests that the presumed mucosal defect is acquired. No precipitating event was discovered. Examination for fecal fat served as a screening test in evaluation of diarrhea in these patients. In view of possible malabsorption during the acute phase of the disease, it is suggested that any critical medication be given by a parenteral route.

- 05 SERUM B₁₂ AND FOLIC ACID IN TROPICAL SPRUE. (E.) Sarin, L. R. (S. M. S. Coll. Med., Jaipur, India), N. M. Kukar and S. R. Mehta. Indian J. Med. Sci. 20(4):253-257, 1966.

24 cases with tropical sprue, serum folic acid levels were reduced in 17, 5 of whom had a concomitant B₁₂ deficiency. Two other cases had only reduced serum B₁₂ levels. In all, there were 3 cases with neurologic manifestations. When all but the latter were admin. folic acid for 6-8 wk. (30 mg/day i.p.), adequate clinical and hematologic responses were obtained; even the lowered B₁₂ levels were corrected in 4 cases. No incidence of precipitated neurological manifestations arose from this treatment. It would appear then that tropical sprue is probably closely related to folic acid deficiency which is often accompanied by a B₁₂ deficiency.

SMALL INTESTINE

Malabsorption

- 8996 GASTROINTESTINAL GAS SYNDROME AS MALABSORPTION SYNDROME. (E.) Goldfarb, M. L. (Meadow Brook Hosp., New York, N. Y.). J. Abdom. Surg. 8(5):122-123, 1966.

A pilot study of 18 patients who complained of severe abdominal pain clearly demonstrated the possibility that this distress is due to gaseous distention caused by mild intestinal malabsorption states. None of these patients suffered diarrhea. In the 6 case histories presented (all under 42 yr. of age) marked gaseous distention of the stomach or splenic flexure was seen on chest X-rays and was relieved by one (or a combination) of the following simple treatments: folic acid, oral vitamin B₁₂, gluten-free diet, calcium lactate and vitamin D. In one case, mental as well as physical disturbances were ameliorated by this treatment. A simple screening test such as prothrombin time or a qualitative stool fat determination would probably serve to detect this condition.

- 8997 STUDIES OF POST-IRRADIATION LOSS OF PROTEINS INTO THE INTESTINE AS INDICATED BY INTESTINAL PERFUSATE IN THE RAT. (Ger.) Zenklusen, G. (U. Bern Switzerland). Acta Isotop. (Padova) 5(2):141-152, 1965.

In rats, i.v. admin. of an iodine-labeled synthetic serum protein (polyvinylpyrrolidone), 1-7 days after whole-body irradiation, was followed by 4 hr. of continuous measurement of the radioactivity of perfusate (Tyrode soln.) introduced into the upper part of the small intestine. During the first 2 days following irradiation, the excretion rate of the synthetic serum protein was below normal expectation. Beginning on day 4, however, it showed a significant increase over the excretion rate seen in non-irradiated controls, with the increased rate peaking on days 5 and 6. The author concludes that the hypoproteinemia which has been observed after whole-body irradiation is due, at least in part, to an enteric loss of protein and that this loss, in turn, results from the fact that the intestinal wall has developed increased permeability for macromolecules.

- 8998 SPECIFIC MALABSORPTION OF VITAMIN B₁₂ WITH PROTEINURIA: PERNICIOUS ANEMIA OF IMERSLUND-NAJMAN-GRASBECK. THREE OBSERVATIONS IN THE SAME FAMILY. (Fr.) Castel, Y. (Cent. Hosp., Brest, France) and Y. Najean. Quest Med. 19(10):573-590, 1966.

Case histories are presented for 3 children (2 male and 1 female) of the same family who developed the Imerslund-Najman-Grasbeck type of pernicious anemia (with vitamin B₁₂ malabsorption and proteinuria) at the age of 16 mo., 2½ yr., and 15 mo., resp. All had clinical signs of megaloblastic anemia, proteinuria, fever, and frequent recurrences; neither achlorhydria, steatorrhea, nor alimentary deficiencies were present. The *in vitro* determination of intrinsic factor in the gastric mucosa (Storb-Najean technic) showed normal levels ranging from 75-104 (units not specified). In the 3 patients, absorption of Co⁵⁸-labeled vitamin B₁₂ (Schilling method) was 0.04%, 0.07%, and 0.20%, resp., without intrinsic factor and 0.05%, 0.01%, and 0.04%, resp., with intrinsic factor. Results show lack of vitamin B₁₂ absorption following p.o. admin. with or without intrinsic factor, when admin. with intestinal juice from a normal subject, or when admin. by stomach tube after the admin. of intrinsic factor or lyophilized guinea pig intestinal powder. Bone marrow function improved after inj. of vitamin B₁₂. No renal or intestinal malformations were observed. Findings are compared with those of other authors. The clinical symptoms, diagnosis, subsequent development, pathogenesis and treatment of the condition are described.

- 8999 MORPHOLOGY AND FUNCTIONAL CYTOLOGY OF THE SMALL INTESTINAL MUCOSA IN MALABSORPTIVE DISORDERS AND OTHER DISEASES. (E.) Fry, L. (King's Coll. Hosp., London, S. E. 5) and R. M. H. McMinn. J. Clin. Path. 19(3):260-265, 1966.

Small intestinal biopsies from 98 patients were studied macroscopically, microscopically, and histochemically, and the results correlated with laboratory and clinical observations. A flat mucosa cannot be considered diagnostic of idiopathic steatorrhea and a convoluted mucosa does not always indicate a pathologic problem. There was a markedly reduced reaction for succinic dehydrogenase in all specimens from patients with celiac disease and idiopathic steatorrhea, but low enzyme

L. INTESTINE

activity is not specific for these diseases since 2 other cases with flat mucosa showed gross deficiencies. There was no correlation between reduced reaction of succinic dehydrogenase and a deficiency of the other enzymes studied, nor between reduced enzyme activity and severity of clinical features. Plasma cell infiltration was a frequent finding in celiac disease and idiopathic steatorrhea, as was a lack of goblet cell metachromasia. In specimens from other conditions, occasional enzyme deficiencies were observed in mucosa that showed normal villi, but these were not as pronounced as in the above-mentioned diseases. If these deficiencies can be confirmed biochemically, then histochemical tests may prove to be useful indicators of abnormal cell function in mucosa that appears normal.

MALABSORPTION SYNDROME. II. SERUM LEVELS OF VITAMIN A AND ITS ABSORPTION IN DIGESTIVE DISEASES. (Cz.) Krondl, A., F. Hrubá, M. Vulterinová, R. Štastná, I. Skála, L. Blahníková, V. Paříková and J. Skála. Cesk. Gastro-ent. Vyz. 20(2):105-119, 1966.

Serum levels of vitamin A were studied in control subjects and in patients with various diseases of the digestive system. They were found to decrease in the following diseases (progressive order of decrease): chronic recurrent pancreatitis, state after acute pancreatitis, state after infectious hepatitis without disturbance of hepatic function, state after Billroth II type gastrectomy (significant decrease = state after cholecystectomy, state after Billroth I type gastrectomy, asthenia, localized damage of intestinal mucosa (SD), small resections of small intestine (SD), extensive disturbances of the pancreas (SD), extensive resections of small intestine (SD), diffuse damage of intestinal mucosa (SD), and chronic hepatitis with impairment of hepatic function (SD). With reference to the serum levels of other substances, there was a significant relationship between the vitamin A level and the cholesterol level, total proteins, and Hb. No such relationship was found with β -carotene, esterified fatty acids, iron, and with vitamin B₁₂ (except in one case after extensive resection of the small intestine). In comparison to controls, the absorption of vitamin A decreased significantly in the following diseases (progressive order of decrease): Billroth II type of gastrectomy (SD), small resection of small intestine (SD), state after acute pancreatitis (SD), Billroth I type of gastrectomy, extensive resections of small intestine (SD), and diseases of the intestinal mucosa (SD). There was no relationship between vitamin A absorption and the blood sugar curve. A significant relationship was found between vitamin A and iron absorption and fecal fat excretion. It was concluded that reduced capacity for absorption of vitamin A or a decreased surface of the absorptive intestinal mucosa leads to a greater drop of vitamin A levels than impaired digestion.

MORPHOLOGIC EFFECTS OF FOLIC ACID AND VITAMIN B₁₂ ON THE JEJUNAL LESION OF TROPICAL SPRUE. (E.) Swanson, V. L. (U. Puerto Rico Sch. Med., San Juan), M. S. Wheby and T. M. Bayless. Am. J. Path. 49(1):167-191, 1966.

Quantitative and qualitative histological changes in jejunal biopsy specimens obtained from 14 patients with tropical sprue before (14 specimens) and after (39 specimens) treatment with large doses of folic acid (7 patients) or with vitamin B₁₂ (7 patients) were evaluated using the dissecting and compound microscopes. Pre-treatment specimens were designated as mildly (4), moderately (6), or markedly abnormal. Following treatment with either folate or vitamin B₁₂, markedly abnormal specimens exhibited a rapid, profound response; the effect on moderately abnormal specimens was prompt and definite, while mildly abnormal specimens exhibited delayed, minimal change. A brisk increase in mitotic activity coincided with an increase in the epithelial cell population, the reappearance of villi, and an increase in overall mucosal thickness, which was nearly complete within 2 wk. Clear abnormalities receded (in 2-10 days in severe cases), and argentaffin cells became less numerous. Abnormal villous patterns tended to persist (unchanged in 7 patients, worse in 2 patients), and changes towards normal (5 patients) were slow. Treatment was continued throughout the period of study, and final biopsy specimens were done 26 days to 1 yr. after initiation of treatment. Residual abnormalities remained in 12 of the 14 patients and appeared to be stationary. In cases of moderate or marked severity the effects of folate given orally were equivalent, both

in time of onset and in magnitude, to those of vitamin B₁₂ by injection. Failure of vitamin treatment to restore the mucosa to normal and the minimal response of mild cases suggest to the authors that there is a basic lesion in tropical sprue upon which changes related to disordered folate-B₁₂ metabolism are superimposed.

- 9002 JEJUNAL BACTERIOLOGY AND BILE SALT METABOLISM IN PATIENTS WITH INTESTINAL MALABSORPTION. (E.) Tabaqchali, S. (Postgrad. Sch. Med., London, W. 12 and C. C. Booth. *Lancet* 2(7453):12-15, 1966.

Small intestinal bacteriology, fecal fat excretion, and bile acid metabolism were investigated in 27 patients with intestinal malabsorption due to partial gastrectomy (17) or blind-loop syndrome (10). Patients with jejunal bacterial counts of less than $40 \times 10^6/\text{ml}$ had no free bile acids and slight steatorrhea. Patients with bacterial counts higher than $100 \times 10^6/\text{ml}$ all had free bile acids in their jejunal fluid and more pronounced steatorrhea. Deoxycholic acid was present in toxic concentration in these patients. Treatment of 6 patients with antibiotics (tetracycline 5; chloramphenicol 1) reduced bacterial counts and caused disappearance of free bile acids from the jejunal fluid. There was a striking reduction in fecal fat. Results suggest that bile acids produced by bacterial hydrolysis may be responsible for steatorrhea in patients with blind-loop syndrome.

- 9003 DISACCHARIDASES AND HISTOLOGY OF DUODENAL MUCOSA IN CONGENITAL LACTOSE MALABSORPTION. (E.) Launiala, K. (U. Helsinki Child. Hosp., Finland), P. Kuitunen and J. K. Visakorpi. *Acta Paediat. Scand.* 55(3):257-263, 1966.

Disaccharidase assays conducted on the duodenal mucosa taken from two infants with congenital lactose malabsorption revealed that lactase and cellobiase activity was practically absent and that maltase, sucrase, isomaltase and trehalase activity was within the normal range. The histological picture of the mucosa was normal in one case (4.5 mo.; male) and only slight, partial villous atrophy was seen in the second case (2.5 mo.; female). Both children had been on a lactose-free diet since a month after birth when breast feeding was discontinued due to persistent diarrhea. It is obvious that these 2 cases of congenital malabsorption arise from an enzymatic defect.

- 9004 VARIABLE CLINICAL COURSE OF ADULT CELIAC DISEASE. (E.) Brooks, F. P. (U. Pennsylvania, Pa.), K. C. Powell and J. J. Cerda. *Arch. Intern. Med.* (Chicago) 117(6):789-794, 1966.

Adult celiac disease is characterized by a grossly flat jejunal lining and a typical microscopic lesion which improves when gluten is removed from the diet. The diagnosis was established in the 11 patients reviewed by small bowel biopsy and quantitative stool-fat determinations before and after treatment with a gluten-free diet. Improvement in mental outlook, disappearance of steatorrhea, appearance of finger-like mucosal villi, wt. gain, lessening of bone pain, return to normal serum levels of calcium and albumin were positive responses seen in some patients after establishment of the gluten-free diet. In this study there was a predominance of female patients, a long duration of symptoms and subnormal folic acid levels (in all patients). Eight patients presented increased daily fecal excretion of fatty acids and an equal number had associated respiratory infections. Only 1 patient had glossitis and only 1 had megaloblasts in the bone marrow. A familial history of celiac disease was found in 3 patients. Hodgkin's disease developed 9 yr. later in 1 patient.

- 9005 CAUSE OF RAISED SERUM-ALKALINE-PHOSPHATASE AFTER PARTIAL GASTRECTOMY AND IN OTHER MALABSORPTION STATES. (E.) Yong, J. M. (St. George's Hosp. Sch. Med., London, S. W. 1). *Lancet* 1(7447):1132-1134, 1966.

An electrophoretic method was used to determine the source of alkaline phosphatase in patients with increased serum levels of this enzyme. Of 14 patients with steatorrhea after partial gastrectomy, 8 had elevated serum alkaline phosphatase from liver, bone, or intestine on 1 or more occasions. Four patients had high activity from increased liver isoenzyme, 1 of whom was later found to have a hepatoma. Only 2 patients showed bone isoenzymes, 1 of whom had clinical evidence of

omalacia and pseudofractures at X-ray. Intestinal alkaline phosphatase was found in 6 patients, none of whom had any evidence of osteomalacia. Analysis of 6 patients with steatorrhea due to causes other than partial gastrectomy showed 6 with normal intestinal and 7 with bone isoenzyme. Data show that the finding of increased intestinal alkaline phosphatase activity in patients with malabsorption syndrome following partial gastrectomy must be interpreted with caution.

VITAMIN B₁₂ ABSORPTION STUDIES: COMPARISON OF ⁵⁷Co VITAMIN B₁₂ PLASMA LEVELS, URINARY EXCRETION AND FAECAL EXCRETION. (E.) Woodliff, H. J. (Royal Perth Hosp., Australia) and B. K. Armstrong. Med. J. Aust. 1(24): 1023-1025, 1966.

Urinary and fecal excretion studies are presented which support the validity of plasma level test as a measure of vitamin B₁₂ absorption, but in no case did they give additional useful information. In 14 patients with vitamin B₁₂ malabsorption, a low urinary excretion of orally admin. Co⁵⁷-tagged vitamin B₁₂ correlated with low plasma levels. In 9 of these patients, from whom feces were collected, high fecal excretion values correlated with the low urinary excretion values and the low plasma levels. In 10 patients with normal vitamin B₁₂ absorption, and 5 patients with vitamin B₁₂ malabsorption corrected by intrinsic factor, a high urinary excretion of Co⁵⁷-tagged vitamin B₁₂ correlated with high plasma levels. In 4 of these, from whom feces were collected, low fecal excretion values correlated with the high urinary excretion values and the high plasma levels.

PRIMARY MALABSORPTION FOLLOWING EXTREME ATTEMPTS TO LOSE WEIGHT. (E.) Pittman, F. E. (Columbia U., New York). Gut 7(2):154-158, 1966.

Two cases with a form of adult celiac disease are described. In both the disorder occurred after strenuous efforts to lose weight. In the first case, a 36-yr.-old male, when, after a month of a diet of turnip greens and a soft drink, he resumed normal diet developed fatigue, listlessness and foul-smelling diarrhea (10-12 stools daily). After 19 mo. and a loss of 105 pounds he was hospitalized. The patient was found to have multiple nutritional deficiencies, steatorrhea, and various neurologic abnormalities. Jejunal biopsy revealed villous atrophy and other changes typical of celiac disease. Once placed on a gluten-free diet the symptoms improved rapidly. Nine mo. later the patient remained symptom-free and continued the gluten-free diet. The 2nd case was a 38-yr.-old female admitted for abdominal pain, weakness, fatigue and foul-smelling diarrhea of 4 wk. duration. Shortly before admission the patient had taken up to 1 pint of milk of amnesia, and a tablet of long acting amphetamine. The laboratory findings were similar to those of the 1st patient. A jejunal biopsy specimen yielded findings similar to those of the 1st case. Within a few days after starting a gluten-free diet the patient's symptoms improved. Ten mo. later she abandoned the gluten-free diet but remained symptom-free. It is suggested that the particular regimens adopted by the patients altered the mucosa of the intestine and made it sensitive to the toxic effects of wheat protein.

RADIOLOGICAL DIAGNOSIS OF DISACCHARIDASE DEFICIENCY. (E.) Laws, J. W. (Postgrad. Sch. Med., London, W. 12) and G. Neale. Lancet 2(7455):139-143, 1966.

A radiological method using a disaccharide/barium-sulfate mixture which is safe, simple, cheap and not unpleasant for the patient is presented for diagnosing disaccharide deficiency. When 5 patients with proven hypolactasia were given a barium-sulfate suspension to which had been added 25 g of lactose, a radiograph made 15 min. later was grossly abnormal in appearance, showing dilution of contrast medium in the small bowel with rapid transit into the colon. With these same patients, the small intestine appeared normal if disaccharides other than lactose were added. In a like manner, 3 patients with proven hyposucrasia showed an abnormal radiograph when sucrose was added to the medium, whereas the radiographs were quite normal if other disaccharides were added. An additional asset of this procedure is that it does not interfere with the normal examination of the esophagus, stomach or duodenum.

- 9009 MALABSORPTION OF METHIONINE. (Dut.) Hooft, C. (U. Ghent, Belgium), J. Timmermans, J. Snoek, I. Antener, W. Oyaert and C. Van Den Hende. Verh. Kon. Vlaam. Acad. Geneesk. Belg. 28(1):15-39, 1966.
A white-haired girl aged 2 yr., 9 mo., with a previous history of scurvy responding to vitamin C, presented with recurrent diarrhea, polypnea and generalized convulsive seizures occurring 3-4 times a day. An electroencephalogram showed characteristic epileptiform spikings in the right hemisphere. Both stools and urine showed abnormally high levels of metabolites of methionine and both branched-chain and other amino acids, with especially high levels of α -hydroxybutyric and other ketoacids. Oral loading tests confirmed that α -hydroxybutyric acid was being formed as a degradation product of methionine, as were α -ketobutyric and α -aminobutyric acids. It was also established that malabsorption of methionine was primary, while malabsorption of other amino acids was secondary to this condition. After 12 mo. of methionine-impooverished diet, the child's hair was blond, instead of white, the electroencephalograph was normal and both diarrhea and convulsions were completely suppressed. The child, who had been classified originally as mentally retarded, also showed a striking improvement of intellectual functioning.

- 9034 THE ANTI-5-HYDROXYTRYPTOPHAN DIARRHOEAL ACTION OF METHYLPHENIDATE (RITALIN) (E.) Ndika, L. I. L. (U. Lagos Sch. Med., Nigeria). Arch. Int. Pharmac. 161(1):242-247, 1966.

Groups of 20 male albino mice were inj. i.p. with 1 mg/kg of 5-hydroxytryptophan and observed for 10 min. for diarrhea. Five groups received simultaneous i.p. inj. of methylphenidate (3 to 16 mg/kg) or amphetamine (80 mg/kg). All doses of methylphenidate decreased the incidence and increased the onset time of the 5-hydroxytryptophan-induced diarrhea, linearly related to dose. Inhibition was 35% with 3 mg/kg, 60% with 9 mg/kg, and 85% with 16 mg/kg. Amphetamine was without activity. It was concluded that this effect is due to a specific anti-5-hydroxytryptophan action of methylphenidate in the gastrointestinal tract.

- 9035 RESULTS OF DUHAMEL'S OPERATION FOR HIRSCHSPRUNG'S DISEASE. (E.) Ehrenpreis, T. (Karolinska Hosp., Stockholm, Sweden), A. Livaditis and L. Okmian. J. Pediat. Surg. 1(1):40-46, 1966.

A 1½-5 yr. follow-up study of 30 children (24 male and 6 female; age 1 mo.-16 yr.) with Hirschsprung's disease treated by Duhamel's procedure from 1959 to 1963 is reported. There was no operative mortality in this series. Among the postoperative complications were leak from rectal stump (2), fecal impaction in the rectal pouch with (6) or without (3) stricture, wound rupture (2), and intestinal obstruction (4); proper surgical treatment resulted in recovery in 16. One patient died following operation for intestinal obstruction, 5 mo. after the initial procedure. Fourteen of the 29 surviving patients were relieved of all symptoms and signs of disease. The remaining 15 patients still have some minor disturbance of bowel and/or bladder function. Persistent constipation was not a problem in this study. Sensory reflexes of the rectum are preserved. Duhamel's procedure has proved to be an easy and safe operation with limited serious complications and can be performed early in infancy obviating the necessity of preliminary colostomies.

- 9036 CARCINOMA OF THE DISTAL LARGE BOWEL: 32-YEAR REVIEW OF 1,026 CASES. (E.) Glenn, F. (New York Hosp., N. Y.) and C. K. McSherry. Ann. Surg. 163(6):838-849, 1966.

The 5-yr. survival rate for each group as a whole, for patients whose cancers were confined to the bowel wall, for patients whose cancers extended through the bowel wall and for patients whose cancers had metastasized to the lymph nodes are reported for 3 patient groups with cancers within or distal to the sigmoid colon. Group 1 consisted of 422 patients treated by abdominal-perineal coloproctectomy; Group 2, of 123 treated by anterior resection; Group 3, of 74 treated by perineal resection, an operation frequently followed by lack of adequate anal sphincter control. Tabulated survival rates for Group 1, as above, were 40.2%, 56.7%, 35.4% and 24.6%, resp.; for Group 2, 43.9%, 75.6%, 28.2% and 23.1%, resp.; for Group 3, 36.5%, 43.3%, 37.5% and 16.7%, resp. Postoperative complications in these 3 groups occurred in 53%, 39% and virtually all patients, resp. Operative mortality rates were 4.7%, 0.6% (1 case) and 14.9%, resp. Intraperineal recurrence was seen in 20.9%, 12.9% and 31.1%, resp. Among 187 patients treated by palliative colostomy (Group 4), the operative mortality rate was 10.7% and av. survival was 9.4 mo, with 3 5-yr., 1 7-yr. and 1 10-yr. survivals + 1 patient still surviving after 10 yr. at the time of report. In these 4 patient groups taken as a whole, operative mortality declined steadily over the 32-yr. period, from 15.4-2.4%, with a 10.4% increase in 5-yr. survivals. Approx. 20% of the patients had a history of colonic polypectomy, showed colonic polyps when first examined or developed such polyps later. Other cancers of the large intestine were present at the time of operation in 5.8%, while 5.9% had a history of previous tumor elsewhere in the body or developed other primary cancers subsequently.

- 9037 HYPOKALEMIA ASSOCIATED WITH SIGMOID VOLVULUS. (E.) Forward, A. D. (U. British Columbia, Vancouver, Canada). Surg. Gynec. Obstet. 123(1):35-42, 1966.

Of 18 male patients (av. age 70 yr.) with sigmoid volvulus treated from 1950-64, overall mortality was 27.8%, with 3 of 5 deaths due to gangrene of the sigmoid loop.

LARGE INTESTINE

due to staphylococcal pneumonia, and 1 to gross electrolyte imbalance. Mucus-like diarrhea was observed in 11 of 18 patients, 8 of whom had been treated by decompression of the sigmoid volvulus with a rectal tube passed through a sigmoidoscope. Five of these 11 presented with significant hypokalemia, but in none was the source of potassium loss considered other than the watery mucus-like rectal discharge. Of the 11 patients, 9 were treated by nonoperative decompression, 7 of whom successfully and 2 died. Of the 7, 4 required further decompression for recurrence and 3 underwent elective resection at a later date. Laparotomy with detorsion was performed in 2 patients and resulted in 2 deaths; Mikulicz resection for obstruction was the primary procedure in 6 instances, with no deaths. The mortality rate in this series is comparable to that of the literature and emphasizes the importance of early diagnosis and definitive treatment in preventing death from gangrene of the sigmoid loop.

- 38 VILLOUS ADENOMAS IN THE COLON AND RECTUM ACCOMPANIED BY ELECTROLYTE DISTURBANCES (McKITTRICK AND WHELOCK'S SYNDROME). (Dan.) Ringsted, A. (Gen. Hosp., Aalborg, Denmark) and J. Wielandt. Nord. Med. 75(20):557-561, 1966.

Review of the literature is supplemented by report of an elderly man who presented with severe diuresis, intractable diarrhea, hypokalemia and acidosis in the presence of papillomatous invasion of the rectal and colonic mucosa. Abdominoperineal extirpation of the rectum, following temporary establishment of normal fluid and electrolyte status, showed a papillomatous adenoma in the rectal ampulla, accompanied by diverticulosis and some degree of diverticulitis of the sigmoid, colonic diverticulosis and chronic colitis. Although electrolyte status was normal after surgery, the patient died in less than a mo. of intercurrent infection and coronary thrombosis.

- 39 IN VITRO UPTAKE OF TRITIATED THYMIDINE BY CARCINOMA OF THE HUMAN COLON. (E.) Lieb, L. M. (Harvard Med. Sch., Boston, Mass.) and H. Lisco. Cancer Res. 26(4):733-740, 1966.

Blocks of tissue (0.5-1.0 cm² and 0.1-0.3 cm thick), excised from colonic adenocarcinomas of 5 patients immediately after resection of the tumors, were incubated for 1 hr. in 100 ml oxygenated Ringer's solution containing 100 μ c of tritiated thymidine with a specific activity of 3.0 c/mmole. After incubation, the blocks of tissue were fixed, embedded, and sectioned. Sections were developed for labeling, stained and prepared for microscopic examination. There was considerable variation in the degree of tritium labeling among the 5 tumors and in different anatomic areas of the same tumor. The labeling index ranged from 3 to 47%. In general, the labeling index was higher than that reported by other investigators using the in vitro technique. It was comparable to results obtained with in vivo uptake of tritiated thymidine in similar tumors. No correlation existed between the incidence of tritium labeling in these 5 tumors and the mitotic indices of tissue samples from the same tumors. The generation time in hr. for the cells of the 5 tumors estimated by exponential growth and steady state formulas were resp.: 1) 28 and 35, 2) 22, and 26, 3) 35 and 45, 4) 112 and 155, 5) 48 and 64.

- 40 A COMPARATIVE ULTRASTRUCTURAL STUDY OF THE MUCOSA IN IDIOPATHIC ULCERATIVE COLITIS, SHIGELLOSIS AND OTHER HUMAN COLONIC DISEASES. (E.) Gonzalez-Licea, A. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and J. H. Yardley. Bull. Hopkins Hosp. 118(6):444-461, 1966.

Mucosal ultrastructures were studied by electron microscopy in rectal biopsy specimens from 7 ulcerative colitis patients and 6 other patients with various intestinal conditions different from colitis. Some in both groups were receiving corticosteroids which did not produce any specific changes in ultrastructures. Various types of lysosomes and related structures were found in all specimens. The presence of cytogrovesomes, dilatation of the endoplasmic reticulum, altered mitochondria and microvilli, as well as ballooning of intercellular spaces, can all be regarded as indications of non-specific cellular damage. Although migration of polymorphonuclear leukocytes into the intestinal lumen occurs in ulcerative colitis, phagocytosis was not observed. It is concluded that the nonspecific ultrastructural changes observed in ulcerative colitis cast no new light on the etiology of the disease.

- 9041 EXCISION OF RECTAL STRICTURE WITH END-TO-END ANASTOMOSIS. (E.) Swenson (Northwestern U. Sch. Med., Chicago, Ill.) and F. S. Idriss. Arch. Surg. (Chicago) 93(1):54-58, 1966.

Eight patients who had been treated for Hirschsprung's disease by resection and pull-through anastomosis and later developed impermeable strictures were operated. The impermeable stricture formation was due, mostly, to delay in performing a diverting colostomy after breakdown of the anastomosis. Successful excision of rectal stricture with end-to-end anastomosis was performed on the patients with no recurrence of stricture. A time-saving technic employing two surgical teams was used on 7 of the patients with case reports presented. The rectal wall was incised from below and a cuff of normal rectum was developed while intra-abdominal dissection and excision of the stricture were being done. The rectum was then everted and a new anastomosis formed. The resection should be limited to the aganglionic portion, and to assure success it should not be done if pelvic inflammation exists.

- 9042 STUDY OF HUMAN RECTAL EPITHELIAL CELLS IN VITRO. II. ³H-THYMIDINE INCORPORATION INTO POLYPS AND ADJACENT MUCOSA. (E.) Deschner, E. E. (Cornell U. Coll. Med., New York, N. Y.), M. Lipkin and C. Solomon. J. Nat. Cancer Inst. 36(5):849-857, 1966.

In vitro studies of thymidine incorporation into rectal tissue samples from patients with abnormal mucosal folds, isolated adenomatous polyps or villous papillomas confirmed a displacement of actively proliferating epithelial cells, not only in all polyp or mucosal-fold tissue but also in areas of mucosa immediately adjacent to the excrescences (i.e., 1-2 cm removed). In tissue derived from healthy subjects, the major incorporation of thymidine was into the lower third of the crypts. In mucosal excrescences and adjacent mucosa (as above) cells which incorporated thymidine were located almost exclusively in the upper third of the crypts and along the free surface of the mucosa. In adjacent mucosa showing evidence of hyperplasia, the phenomenon was always present; in adjacent mucosa which was macro- and microscopically normal in appearance, it was found only on occasion, suggesting that these might be potential foci of future polyp activity which had not yet reached the point of hyperplasia. It is concluded that these data lend support to the concept that papillomas and adenomas both derive from surface epithelium.

- 9043 RESULTS OF TREATMENT OF COLONIC WOUNDS. (Fr.) Razemon, P. (U. Lille Sch. Med., France), C. Gautier and J. Dhainaut. Lille Chir. 21(2):189-192, 1966.

In a group of 8 men who were operated for abdominal gunshot or stab wounds, a median incision, beginning just above the umbilicus, permitted exploration of the entire abdominal cavity (extended, when indicated, as far as the thorax), followed by immediate, extramucosal suture of penetrated areas with non-resorbable sutures. Seven had no postoperative complications; 1 developed a fistula which healed spontaneously. Colostomy was performed on 2 other patients in the presence of multiple wounds and acute shock. It is concluded that, except in the presence of shock which jeopardizes survival (when colostomy is justified), the procedure described is the surgery of choice when such situations are encountered in civilian practice. Also described are 2 patients who developed abscesses (treated successfully) following other types of surgical intervention and 2 patients who died of multiple gunshot wounds involving most of the viscera.

- 9044 DIET AND DIVERTICULITIS. (E.) Cleave, T. L. and G. D. Campbell. Brit. Med. J. 2(5504):50-51, 1966.

As the consumption of unrefined maize (hominy) has progressively declined in the United States particularly since the 1920s, the incidence of diverticular disease of the colon among those of the Negro race has progressively increased. This condition is virtually non-existent among members of this race who live tribally in Africa and whose carbohydrate diet is unrefined, consisting of the coarsest maize and includes little sugar. By contrast, in the United States presently the Negro's carbohydrate diet is mainly white flour wherein there has been a massive removal of fiber plus an ever-increasing amount of sugar. This diet results in a marked slowing of the passage of colonic content which predisposes one for diverticulitis.

- 45 ADENOCARCINOMAS OF THE ANAL CANAL AND PERI-ANAL TISSUES. (E.) Cabrera, A. (Roswell Park Mem. Inst., Buffalo, New York), Y. Tsukada and J. W. Pickren. Ann. Surg. 164(1):152-156, 1966.

a series (taken over a 43-year period) of cancers of the anal canal and perianal region, the incidence of adenocarcinoma was 6.6%. Of these 8 cases whose ages ranged from 28-75 yr., 2 patients were free of neoplastic disease after abdominoperineal resection for about 3 yr. A third patient treated in this manner died 1 yr. and 3 yr. after the operation: the postmortem disclosed extensive metastases. Ionizing radiation did not affect the tumors appreciably; the 4 patients treated with radiation died 1/2, 2, 2 1/2, and 4 yr. after the initial symptoms. The growth of this type tumor was rapid: the av. time between initial symptoms and death was 2.8 yr.

- 46 CAECOCOLIC INTUSSUSCEPTION IN IBADAN. (E.) Cole, G. J. (U. Hosp., Ibadan, Nigeria.). Brit. J. Surg. 53(5):415-419, 1966.

an area in western Nigeria of less than 100 miles length shows a remarkably high incidence of cecocolic intussusception. The av. age of 100 patients reviewed was 10 yr.: ages 5 through 10 was the 10-yr. span with the greatest number of patients. Such symptoms as pain, vomiting, diarrhea and melena were notably less severe than those seen with ileocolic intussusception. Those patients over 10 yr., of age with illness of 14 days (av. duration was 18 days) showed an approximate correlation between the extent of the intussusception and the duration of symptoms. In contrast, those between 2 and 10 yr. of age showed an irrational progression: sometimes the appendix had passed the sigmoid colon in a few hr., while other times it had not negotiated the hepatic flexure after a wk. of symptoms. When the appendix had passed the sigmoid colon, mortality and gangrene became dangerous possibilities (4 deaths resulted in this group). Of the 100 patients, 16 had obstruction; a mass was obvious in 66 patients. Surgical reduction was possible in all but 9 cases where resection was necessary. There were 4 recurrences. The dietary factors which might explain this localization of cecocolic intussusception in this area are discussed.

- 47 SURGICAL TREATMENT OF ULCERATIVE COLITIS. (Nor.) Sanderud, A. (Nat. Hosp., Oslo, Norway). T. Norsk. Laegeforen. 13(1):981-985, 1966.

A statistical review was made of 84 patients (45 male, 37 female, 2 not specified) treated for ulcerative colitis over a period of 15 yr. Incidence by age groups was as follows: 10-20 = 12; 20-30 = 15; 30-40 = 25; 40-50 = 20; 50 or over = 12. Among those receiving only medical treatment, 2 of 14 died before surgery could be instituted; 1 of 14 was lost to follow-up; 1 of 14 had responded poorly over 5 yr. and was agreeable to surgery at the time of report; 10 of 14 were alive and able to follow normal occupations after 3-9 yr. of observation. Surgical procedures included colostomy (20 patients; 6 of 20, included below, as a second surgical intervention), partial colonic resection + enteroanastomosis (3), subtotal colonic resection + extirpation of the proctosigmoid (4), subtotal colectomy + colostomy (10), ileoproctostomy (16) and total proctosigmoid colectomy + ileostomy (23). Histologically confirmed adenocarcinomas were found in 6 of 84, 11-21 yr. after initial diagnosis of ulcerative colitis. All cancers were multiple. Atypical polyps were found in 3 of 84. Ten of 84 patients died in the immediate postoperative period; 5 of 84, during the first 3 postoperative mo. Among patients undergoing ileoproctostomy + pancolectomy, 8 of 39 developed postoperative ileus requiring rehospitalization. Among men undergoing total colectomy, 2 of 23 developed relative impotence; 1 of 23, total impotence.

- 48 PATHOPHYSIOLOGY OF MECHANICALLY-INDUCED ILEUS. I. EXPERIMENTAL STUDIES, WITH PARTICULAR REFERENCE TO THE CIRCULATION AND TO INTRACELLULAR CONCENTRATION OF ELECTROLYTES. (CONTINUATION.) 4. DISCUSSION. (Ger.) Staib, I. (U. Marburg, Germany). Bruns Beitr. Klin. Chir. 212(4):385-416, 1966.

In dogs and rats, mechanically induced intestinal strangulation was accompanied by a significant reduction of intracardiac blood flow; apparently due to disturbance of venous return rather than reduced cardiac efficiency as such. There were no significant changes in terms of hematologic values such as hematocrit, hemoglobin, erythrocyte count or volume, etc., or in terms of intra- or extracellular fluid volume. In the liver, both intra- and extracellular K and Na were diminished; but K in the

musculature was unchanged, although the Na level was elevated. Electrolyte levels found in the small intestine were the same for segments oral and aboral to the site of strangulation, except in the presence of macroscopically discernible gangrene. In some animals, elevation of extracellular K and inorganic phosphates appeared to parallel the degree of increasing metabolic acidosis, decreasing hepatic intracellular K and progressive deterioration of clinical condition. No correlation with the degree or type of ileus was shown by measurements of membrane potential or total base or by either absolute values or quotients of total proteins, albumin or globulin. Serum creatinine was unchanged as long as circulation and kidney function were intact. Endotoxins accumulated primarily in the liver, spleen and lungs. In rats, substitution therapy with amounts of K up to 8 times normal failed to influence the progressive intracellular defect with respect to this substance. It is concluded that extracellular electrolyte changes can be delayed or partially offset by substitution therapy; but this does not necessarily influence intracellular changes significantly, since these are sequelae of a generalized metabolic dysfunction. In problem patients, it is suggested that electrolyte balancing should be based on determinations of intra-, rather than extracellular electrolyte contents.

- 9049 SURGICAL TREATMENT OF CANCER OF THE LEFT COLON AND RECTUM. TECHNIC AND RESULTS. (It.) Imperati, L. (U. Rome) and M. Cagetti. Bull. Soc. Int. Chir. 25(2):145-153, 1966.

Of 411 patients operated for cancer of the left colon and rectum, surgery was radical in 325 (79.1%), palliative in 49 (11.9%), and explorative in 37 (9%). Radical surgery consisted of abdomino-perineal excision (Hartmann or extended Miles) in 32.9% and resection in 67.1%. The type of cancer was simple in 71.3%, complicated in 17.7%, and diffuse in 11%. Tumor sites included the descending colon (11 patients), sigmoid (57), rectosigmoid junction (62), rectum (159), anal canal (24), and recto-colonic polyposis (12). Complications of surgery included cardiac insufficiency (15 patients), respiratory disturbances (9), peritonitis (16), pelvic suppuration (18), colonic fistula (8), and obstruction (6). Operative mortality was 10.1% (33 patients), 14 after abdomino-perineal excision and 19 after resection. Five-yr. survival was 52.2% following abdomino-perineal excision, 59.13% for resection, and 55.93% for both combined. Functional results were better after resection than after abdomino-perineal excision.

- 9050 ON THE SPECIFICITY OF AUTOANTIBODIES PRESENT IN COLON CANCER PATIENTS. (E.) Von Kleist, S. (Inst. Sci. Res. Cancer, Villejuif/Seine, France) and P. Burtin. Immunology 10(6):507-515, 1966.

The sera of 223 subjects were tested (53, colon carcinoma; 83, carcinoma of other organs; 53, intestinal disorders other than cancer, and 34, healthy individuals). Tumor tissue, surgically removed, was obtained from 85 individuals. Normal tissue was obtained from 24 persons as well as from a number of fetuses. Standard immunologic procedures were used in this study, including passive hemagglutination technique, sera absorption tests and enzymatic treatment of tissue extracts as well as precipitation tests. The incidence of high agglutinating titers (1:160 or more) was much greater (52%) in sera of patients with colonic cancer than in control sera (3%) which suggests an immune response by the host against the tumor. The sera of 14 patients giving high titers of hemagglutination were from patients with cancer in sites other than the colon. Patients with ulcerative colitis in some cases had high titers of hemagglutination. Precipitation tests produced a few results but of unknown specificity. The preliminary enzyme studies were not detailed enough to determine the chemical nature of the antigen. The comparative absorption studies strongly indicate that at least 2 antigen-antibody systems are involved.

Ulcerative Colitis

- 9129 RESPONSE TO AZATHIOPRINE IN ULCERATIVE COLITIS. REPORT OF 7 CASES. (E.) Mackay, I. R. (Royal Melbourne Hosp., Victoria, Australia), A. J. Wall and G. Goldstein. Am. J. Dig. Dis. 11(7):536-545, 1966.

Results are reported after long term treatment of 7 patients with ulcerative colitis with 6-mercaptopurine or azathioprine. Initial or maintenance treatment with corticosteroids or ACTH was admin. to 3 patients. Of 2 female patients treated with 6-mercaptopurine (100-150 mg/day) for 3 wk. to 13 mo., 1 had complete remission for 2 yr. after cessation of treatment and 1 (a 60-year-old debilitated patient) showed poor clinical response and died post-colectomy. Of 5 other patients (4 men and 1 woman; age 16-27 yr.) treated with azathioprine (100-200 mg/day) for periods of 3-12 mo., 1 is in full remission after 15 mo.; 1 has mildly active disease after 12 mo. of treatment; 1 has inactive disease after 12 mo.; 1 was in remission for 5 mo. but then developed abdominal pain and died after subtotal colectomy; 1 is in remission after loop ileostomy without colectomy. An addendum indicates that an additional patient with severe disease was treated for 1 mo. with azathioprine (200 mg/day); partial improvement and lymphoid recession in the rectum were observed, but colectomy is planned. The most noteworthy effect of this treatment was marked decrease in lymphoid infiltration in the rectal mucosa.

- 9130 IMMUNOLOGICAL STUDIES IN ULCERATIVE COLITIS. III. INCIDENCE OF ANTIBODIES TO COLON-ANTIGEN IN ULCERATIVE COLITIS AND OTHER GASTRO-INTESTINAL DISEASES. (E.) Lagercrantz, R. (U. Stockholm, Sweden), S. Hammarström, P. Perlmann and B. E. Gustafsson. Clin. Exp. Immun. 1(3):263-276, 1966.

Of 101 patients with ulcerative colitis, 56% were found to have a hemagglutination titer of greater than 1:16; whereas, of 45 healthy controls or surgical cases who were age- and sex-matched, only 13% had such high titers. In ulcerative colitis, the incidence of elevated titers was independent of duration or severity of the disease, the extent of colonic involvement or the occurrence of extracolonic manifestations. The incidence was independent of age as well, except that it was significantly higher in females older than 25 yr. than in male patients of the same age. Colectomy (including pancoloproctectomy) was without influence on antibody titers which sometimes remained elevated 2-10 yr. postoperatively. Of 109 patients with other gastrointestinal disorders (chronic diarrheas of unknown etiology, bacillary dysentery, Salmonella infections, cancer of the colon and rectum and celiac disease) only 8 had a titer of greater than 1:16. Of 18 patients with regional enteritis, 67% had such a high titer, but 11 of these patients had lesions in both the large and small intestine. Patients with amebic dysentery or bronchial asthma had a greater incidence of high titers than the controls and a lower incidence than those with ulcerative colitis. Fluorescent antibody staining of rat colon sections correlated with and confirmed these results.

- 9131 DELAYED HYPERSENSITIVITY IN REGIONAL ENTERITIS AND ULCERATIVE COLITIS. (E.) Binder, J. H. (Yale U. Sch. Med., New Haven, Conn.), H. M. Spiro and W. R. Thayer, Jr. Am. J. Dig. Dis. 11(7):572-574, 1966.

Normal delayed hypersensitivity to mumps skin test antigen, Candida albicans (oidiomycin) extract, and Trichophyton gypseum was observed in a group of 41 patients with regional enteritis (Group 1 - 16 patients), ulcerative colitis (Group 2 - 16 patients), and granulomatous colitis (Group 3 - 9 patients). Nineteen other patients served as controls. More than 0.5 cm of erythema or induration 24 hr. after the intradermal inj. of 0.1 ml of the antigen was considered to be a positive response; 63% of Group 1, 81% of Group 2, 67% of Group 3, and 89% of the controls showed delayed hypersensitivity to mumps; the respective figures for response to oidiomycin are 67%, 81%, 86%, and 95%; and to Trichophyton 73%, 44%, 57%, and 68%. The results are interpreted as being further evidence against any relation of regional enteritis to sarcoidosis.

- 9132 RECENT STUDIES ON ULCERATIVE COLITIS IN CZECHOSLOVAKIA. (E.) Maratka, Z. (Charles U., Prague, Czech.). Am. J. Gastroent. 45(6):460-471, 1966.

Of 189 patients with severe ulcerative colitis seen during the past 24 yr., 100 were

treated surgically; 31 had proctocolectomy with permanent ileostomy, 34 had colectomy with ileorectal anastomosis, 5 had palliative procedures, and 30 operations were uncompleted. Since 1960, colectomy with excluded ileorectal anastomosis in 2 stages has become the method of choice, not only to provide more normal defecation but also to effect better reabsorption of fluid and electrolytes and to prevent urolithiasis. The incidence of urolithiasis was found to be 27% in 30 patients with permanent ileostomy, 11% in 35 patients with temporary ileostomy, 3% in 31 patients with ileorectal anastomosis, and 2.2% in 89 patients not treated surgically. Balance studies in patients with long-established ileorectal anastomoses (Group 1 with 11 patients) or ileostomies (Group 2 with 4 patients) showed greater average daily excretion of fluids and Na via the gastrointestinal tract in Group 2 (514 g of dejecta and 64.7 mEq of Na) than in Group 1 (410 g of dejecta and 46.6 mEq of Na); daily output in the urine was 731 ml of water and 75.3 mEq of Na for Group 2 and 969 ml of water and 98 mEq of Na for Group 1. The surgery is usually divided into several stages (1 - ileostomy with exclusion of a loop of terminal ileum; 2 - colectomy with side-to-end anastomosis of excluded ileum with rectum; 3 - side-to-side ileo-ileoanastomosis) because of the lower mortality (9% of 44 patients) with staged than with single (30% of 33 patients) operations. Thirty-three liver biopsies from 26 patients have revealed steatosis in most patients with severe disease; the condition improves following ileostomy, and the biopsy findings, along with other criteria, are of aid in timing the colectomy.

- 33 SURGICAL TREATMENT FOR PEDIATRIC ULCERATIVE COLITIS. (E.) Levin, P. (U. California, Los Angeles), E. W. Fonkalsrud and W. F. Barker. Surgery 60(1):201-211, 1966.

The results of medical and surgical treatment of ulcerative colitis in 54 in-patients (mo.-16 yr. at onset of symptoms) are reported. All patients were initially treated medically with special diet and fluid and electrolyte therapy; some received steroids, sulfonamides, antianemic agents, and psychotherapy. Of the 25 patients who received medical treatment only, 3 have had complete remission of symptoms for 2 yr., 2 have been in good control, 7 in poor control, 1 died, and 1 have been lost to follow-up. Twenty-nine patients (53.7%) required operation because of impending abdominal catastrophe (15 patients) or chronic debilitation despite maximum medical treatment. Subtotal colectomy and ileostomy were performed in 19 patients, total colectomy and permanent ileostomy on 9 patients, and subtotal colectomy followed by ileorectal anastomosis on 1 patient; 5 patients of the first group later required proctectomy because of persistence of disease in the rectal segment. Of the 29 operated patients, 16 (including a 4-mo.-old infant) have had excellent results (7 after subtotal colectomy, 6 after total colectomy, and 3 after subtotal colectomy followed by proctectomy); 9 have had good results (6 retain diseased rectums after subtotal colectomy, and 2 required additional operations for post-operative complications); 3 died and 1 was lost to follow-up. Thirteen patients (44.8%) developed multiple postoperative complications; most patients with severe complications and all who died had received steroids preoperatively, and most had had emergency operations. Pre- and postoperative management is described. The authors recommend the omission of steroids and the consideration of elective operation earlier in the course of the disease and discuss the desirability of various types of operation.

EXOCRINE PANCREAS

- 49 RESULTS OF CEPHALIC DUODENOPANCREATECTOMY IN THE TREATMENT OF PATIENTS WITH PANCREATIC CALCULI. BASED ON 42 CASES. (Fr.) Guillemin, G. (Municipal Hosp., Lyon, France), J. Dubois, G. Braillon, E. Naudin, J. Cuilleret, J. Feroldi, J. Cornet and J. Gilly. Ann. Chir. 20(5-6): 424-437, 1966.

Among 42 patients with advanced pancreatic lithiasis, the primary etiologic factor appeared to be alcoholism (with or without associated pancreatitis) in 34 cases. Clinical symptoms included pain resulting from pancreatic retention, emaciation, jaundice, duodenal stenosis, segmental portal hypertension due to splenoportal compression, exocrine insufficiency and (in far-advanced cases) diabetes. Surgery consisted of extirpation of the head of the pancreas and duodenal section at the third division, at the level of the genu inferius. This was followed by cholecystectomy and resection of the common bile duct at the lowest possible point. Continuity was reestablished by successive implantation of the remnant of the pancreas, the remnant of the bile duct and the stomach on an omega loop, followed by construction of an extensive jejunojejunostomy at the foot of the loop. There was one operative mortality, due to difficulties with anesthesia, and 4 patients died subsequently of non-related causes. Postoperative complications included 5 cases of transient leak of bile fluid, 1 spontaneously healing biliary fistula and 1 acute pancreatitis developing in the pancreatic remnant. Among the 37 survivors, results were tabulated as excellent (23), good (11), fair (1) and unsatisfactory (2), 6 months after surgery.

- 50 EARLY RESULTS OF THE FLUORESCENCE TEST (TETRACYCLINE) IN THE COURSE OF THE DOUBLE SECRETIN-PANCREOZYMIN TEST. (Fr.) Plessier, J. (Saint Antoine Hosp., Paris), Economidou and B. Plessier. Acta Gastroent. Belg. 29(2):179-182, 1966.

The value of the tetracycline fluorescence test in the differential diagnosis of pancreatic disease was studied after secretin stimulation in 52 apparently normal subjects and 8 patients with pancreatic cancer. Positive fluorescence following pancreozymin was considered of no value due to the large size of the fluorescent spot. Among controls, results were negative in 50, doubtful in 1, and positive in 1 (a patient with calcifying chronic pancreatitis in whom surgical confirmation was not possible). Among cancer patients, results were positive in 6 and negative in 2. In the 2 negative patients, complete absence of pancreatic juice due to obstruction of the pancreatic duct (confirmed at surgery) was observed, although the presence of jaundice and an enlarged gallbladder was sufficient to make the diagnosis. Pancreatic cancer was confirmed at surgery in the 6 patients with positive fluorescence.

- 51 RUPTURE OF SMALL DUCTS AND ACINI IN THE PANCREAS OF THE RAT AND GUINEA PIG FOLLOWING MAJOR DUCT OBSTRUCTION. (E.) Herriott, B. A. (Sydney Hosp., Australia) and A. A. Palmer. Aust. J. Exp. Biol. Med. Sci. 44(2): 143-155, 1966.

Following obstruction of the pancreatic duct system in the rat or the guinea pig, rupture of pancreatic acini and ductules was clearly defined by the periodic acid-Schiff (PAS) technic. In rats, such ruptures were also demonstrated following a pancreaticobiliary obstruction by interposing an ink-filled tube between the hepatic and common ducts. In the rats, the number of ruptures varied greatly: the maximum was seen in those sacrificed 12 or 18 hr. after obstruction. At the end of 1 wk., all the changes noted at 48 hr. had progressed. When common-channel biliary obstruction was also performed, the histological results were only changed slightly: hemorrhage in the wall of the common duct and more frequent and severe acinar necrosis in the first 18 hr.

- 52 SURGICAL TREATMENT OF PANCREATIC CYSTS: REVIEW OF 183 CASES. (E.) Warren, K. W. (Lahey Clin. Found., Boston, Mass.), S. Athanassiades, P. Frederick and G. A. Kune. Ann. Surg. 163(6):886-891, 1966.

Among patients treated surgically for pancreatic pseudocysts, tabulation was made

EXOCRINE PANCREAS

of the number treated by a particular procedure (total of 93 procedures in 79 patients), the number of satisfactory outcomes, the number of poor responses and the number in whom cysts recurred, as follows: external drainage = 35, 19, 16 and 5, resp.; internal drainage = 24, 20, 4 and 0, resp.; resection or excision = 26, 19, 7 and 2, resp.; transduodenal sphincterotomy = 8, 6, 2 and 0, resp. Similar tabulations among patients with retention cysts (total of 65 procedures in 61 patients) were: external drainage = 5, 4, 1 and 0, resp.; internal drainage = 5, 5, 0 and 0, resp.; resection or excision = 41, 33, 8 and 0, resp.; sphincterotomy = 14, 9, 5 and 3, resp. Similar tabulations among patients with traumatic cysts (total of 21 procedures in 15 patients) were: external drainage = 6, 3, 3 and 2, resp.; internal drainage = 7, 4, 3 and 1, resp.; resection (distal pancreatectomy) = 6, 6, 0 and 0, resp.; sphincterotomy = 2, 1, 1 and 0, resp. Resection or excision of a cystadenoma in 8 patients yielded 7 excellent results and 1 operative mortality. There were no recurrences. Four patients who underwent excision of a cystadenocarcinoma and resection of the surrounding area of the pancreas were alive and well 10-12 yr. after surgery, although patients treated by external drainage (2), internal drainage (1) or excision of the cyst alone (2) all died of metastases. A group of patients with retention cysts secondary to carcinoma of the head of the pancreas was treated by external drainage (3), internal drainage (2), or resection (5). All died of metastases within a short time. Av. survival time in this group was 9 mo.; the longest survival time, 18 mo.

- 9153 PANCREATIC TRAUMA: REVIEW OF 23 CASES. (E.) Barnett, W. O. (U. Mississippi Med. Ctr., Jackson), J. D. Hardy and R. L. Yelverton. Ann. Surg. 163(6):892-901, 1966.

Among 23 patients with pancreatic trauma resulting from automobile and other accidents (11), gunshot wounds (7) or surgical interventions (5), non-penetrating injuries (chiefly, contusions or lacerations with several instances of subsequent pseudocyst formation) were treated successfully by drainage, cystogastrostomy or resection of pancreatic tissue distal to the site of injury. In most cases, early diagnosis was made on the basis of signs and symptoms of acute abdomen. Penetrating pancreatic injuries were treated successfully by suture and drainage or, in 2 of 3 cases in which maceration had occurred, by excision of the tail of the pancreas. Intraoperative trauma included creation of a false passage into the pancreas during common bile duct exploration, injuries due to improper handling of retractors during surgery, inadvertent injury of the pancreatic tail during an adrenalectomy and division of both the pancreatic and common bile ducts during a gastric resection. Non-penetrating injuries were accompanied by rupture of the pancreas, spleen or duodenum; hepatic laceration; retroperitoneal hematoma; transection of the common bile duct; bone fracture and/or cerebral contusion. Penetrating injuries were accompanied by perforations of the stomach, duodenum, colon, mesocolon, spleen, diaphragm and/or pleural cavity. No deaths resulted from surgical treatment of the pancreatic trauma, although 3 of the 23 patients died of other causes associated with the trauma or its source. Preoperative serum amylase levels proved unreliable as indications of the presence or absence of pancreatic injury, and several of the injuries were detected only several mo. after the accident which caused them. It is concluded that all abdominal explorations for suspected trauma should include exposure and examination of the pancreas.

- 9154 INFLUENCE OF PANCREAS ON IRON RESORPTION. (Ger.) Dittrich, H. (Hanusch Hosp., Vienna, Austria), I. Hölbl and E. Seifert. Med. Klin. 61(25):1002-1005, 1966.

Fe resorption was investigated in 25 patients with various degrees of fatty liver (diagnosis established by biopsy), after admin. of 200 mg of a bivalent Fe preparation (fasting blood level and 3 times at 2 hr. interval after intake); the tests were repeated 1 wk. later, at which time a pancreatic enzyme preparation was also admin. Seven of the 25 patients had normal serum Fe levels (80-150 µg%) which rose only moderately during the test. These patients were considered normal. Another 7 of 25 had 130-200 µg% initial serum Fe levels remaining practically unchanged during the tolerance test. The remaining 11 of 25 patients had fasting Fe levels over 200 µg%; nevertheless rapid uptake took place, comparable to conditions of Fe deficiency, even though patients had more than an adequate supply of Fe.

ENDOCRINE PANCREAS

min. of the pancreatic enzyme (second test) reduced Fe uptake in 2 patients of the first (normal) group, had no effect on patients of the second group, but reduced considerably the Fe uptake in 8 of 11 of the last group. Case histories showed that 5 of 25 patients were heavy drinkers or chronic alcoholics; all 10 favorable responses to the pancreatic enzyme belonged to this category of 15. It is assumed that the pancreas secretes a heat-labile factor which inhibits Fe resorption; the factor seems to be missing (decreased) in pancreatic damage due to chronic alcohol consumption.

155 PHARMACOLOGICAL EFFECTS ON PANCREATIC BLOOD FLOW. (E.) Papp, M. (Inst. Exp. Med., Hungarian Acad. Sci., Budapest), B. Varga, Z. Acs, I. Krasznai and J. Földes. Arch. Int. Pharmacodyn. 161(1):61-67, 1966.

Blood flow in the pancreas and kidney of anesthetized dogs was studied by flexible heated thermocouples and by inj. of 30 μ c of rubidium⁸⁶. Pancreatic blood flow was more than doubled by dehydrocholic acid (10 ml of 10% soln. i.v.), increased over 100% by histamine (1 mg i.v.) but not changed by epinephrine (25 μ g i.v.); kidney blood flow was decreased 50% after histamine and epinephrine but unchanged by dehydrocholic acid. The effect of dehydrocholic acid on pancreatic blood flow was confirmed by the rubidium⁸⁶ method when blood flow was found to increase from 5.9 to 126.1 ml/min./100 g gland. Dehydrocholic acid did not change cardiac output or blood pressure but did significantly lower pancreatic arterial resistance.

156 THE EFFECT OF RADIATION ON THE FINE STRUCTURE AND ENZYME CONTENT OF THE DOG PANCREAS. II. LONG TERM STUDIES. (E.) Wellmann, K. F. (Jewish Chron. Dis. Hosp., Brooklyn, N. Y.), B. W. Volk and A. Lewitan. Lab. Invest. 15(6):1007-1023, 1966.

After a single heavy dose of roentgen rays (5000 to 9000 r), the acinar cells' fine structure of the exteriorized residual pancreas from 17 partially depancreatized dog passed from a degenerative phase after the 2nd or 3rd postirradiation mo. to a recovery phase, which peaked during the 3rd and 4th mo., and gradually reached normal by the 6th-9th mo. In contrast, the pancreatic tissue activities of amylase, leucine aminopeptidase and lipase showed greatly diminished values to the very end of the yr.-long observation period. Of the same 3 enzymes measured in the serum, only lipase showed permanently decreased activity from the 3rd mo. on. This discrepancy between structure and function might be due to damage to the endoplasmic reticulum and the Golgi apparatus which is not visible with the present techniques. The pancreatic β cells went through similar phases of ultrastructure alterations but they were less pronounced. The function of the pancreatic β cells remained unimpaired throughout. The pancreatic α cells displayed only occasional minor structural alterations.

157 TREATMENT OF MUCOVISCIDOSIS AT THE GIENS CENTER. RECORD OF THREE YEARS OF ACTIVITY. (Fr.) Gilly, R. (Renée-Sabran Hosp., Giens, France) and G. Chevallier. Arch. Franc. Pediat. 23(3):335-345, 1966.

The first center established in France for intensive treatment of children with cystic fibrosis received 50 cases in the course of the 1st 3 yr., coming from 49 different families with a total of 145 children. Anamnestic investigation showed that 59/145 were in good health; 53/145 were suffering from cystic fibrosis and 33/145 were decreased (12/33, of verified cystic fibrosis; 12/33 of probable cystic fibrosis; 9/23 of possible cystic fibrosis in the light of clinical histories). Among patients received at the center (29 boys, 21 girls), 27/50 were less than 1 yr. old, 9/50 were aged 1-3, 14 were more than 3 yr. old. In addition to symptomatic treatment and treatment of nutritional deficiencies, intercurrent infections, etc., liquefaction of abnormal mucus was attempted by aerosol treatment with N-acetyl cysteine (Mucomyst) for 10-15-min. intervals 3 times a day, followed by postural drainage, vibration, thoracic percussion, etc. Children slept at night in oxygen tents under vapor containing distilled water, sodium chloride and propylene glycol. Associated treatments included corticosteroids, bronchial aspiration, occasional direct instillation of N-acetyl cysteine in children over 3. The overall mortality rate was 12% (11% among infants; 22% among children over 3). The av. duration of treatment was 6-8 mo. Among children treated for a mean interval of

EXOCRINE PANCREAS

6 mo., at the time of report 33/42 showed normal or near-normal weight; 32/42 showed favorable chest X-rays; 18/42 had total "scores" (per a system of values assigned to nutritional condition and chest X-rays) which were in the "good" range.

- 9158 THE INFLUENCE OF PANCREATIC DUCT LIGATION ON THE COURSE OF E. coli ENDOTOXIN SHOCK IN THE DOG. (E.) DeKoos, E. B. (Montreal Gen. Hosp., Quebec, Canada), W. J. Gibson, G. Bounous and L. G. Hampson. Canad. J. Surg. 9(3):227-236, 1966.

Mongrel dogs with an av. wt. of 13 kg were divided into a control group (8 dogs) and an experimental group (6 dogs). All dogs were anesthetized during the experiment. The control dogs received i.v. 3 mg/kg endotoxin of Escherichia coli at the beginning of the experiment. Arterial blood pressure was monitored by means of a carotid cannula coupled to a Statham strain gauge recording on a Grass polygraph. Cardiac output was determined at intervals by the dye dilution method. Hematocrit, heart rate, lactate and pyruvate levels were also determined. Peripheral resistance was calculated from cardiac output and blood pressure values. The 6 dogs of the experimental group underwent sterile ligation of the pancreatic ducts 4-5 days prior to shock induction to eliminate pancreatic enzymes from the intestinal tract. Endotoxin was admin. as in the control group, and the same parameters were measured. Both control and experimental animals survived for an av. of 3 hr. after inj. of endotoxin. The most striking feature in the experimental dogs was the complete absence of hemorrhagic necrosis and congestion in the small bowel. Bowel changes were classical and extensive in the control group. Although survival time was not increased among the experimental animals, there were some differences in the measured parameters. Hemoconcentration was very slight among the experimental dogs (hematocrit 48 rising to 49%), whereas blood plasma volume loss was severe in the controls (hematocrit 46 rising to 61%). Lactate levels rose more sharply in the experimental animals. The peripheral resistance very nearly tripled in the control; in the experimental dogs the increase was little more than half the original value.

- 9159 THE EFFECTS OF 250-Kv X-RAYS ON THE DOG'S PANCREAS: MORPHOLOGICAL AND FUNCTIONAL CHANGES. (E.) Archambeau, J. (Argonne Cancer Res. Hosp., Chicago, Ill.), M. Griem and P. Harper. Radiat. Res. 28(2):243-256, 1966

The pancreas of 14 dogs was surgically isolated to the right side of the abdomen to facilitate irradiation of the gland; 5 dogs served as surgical controls; 9 dogs each received a total dose of 4500-5000 rads of 250 kvp X-ray fractionated over 30 days. Histological changes observed at the end of irradiation, 1 mo., 2 mo., and 5 mo. post-irradiation, demonstrated a progressive interstitial fibrosis and scarring which distorted the normal architecture. The acini were morphologically intact although separated by fibrosis. The islets showed no change; α and β cells were present. There was no indication of cell loss or degeneration. One dog with a total pancreatic fistula survived 2 wk. after receiving 4500 rads fractionated over 24 days. The total 24-hr. secretory vol. and the secretory vol. after secretin and Mecholyl stimulation remained unchanged, during and after irradiation. The electrolytes of the serum and of the pancreatic secretion remained within normal limits as did fasting blood sugar. Glucose tolerance tests were normal. However, the elevated serum amylase decreased as the conc. of amylase in the pancreatic secretion increased. These studies indicate that the pancreas shows few morphological or functional changes following high dose fractionated irradiation.

- 9160 ALTERATIONS IN HUMAN THORACIC DUCT LYMPH IN RELATION TO THE FUNCTION OF THE PANCREAS. (E.) Bartoš, V. (Charles U., Hradec Kralove, Czech.), V. Brzek and J. Groh. Am. J. Med. Sci. 252(1):65-72, 1966.

The thoracic duct lymph in man seems to have an important role in the transport of pancreatic enzymes (amylase and lipase) under physiological conditions and measurement of their conc. in the lymph might have diagnostic value for the detection of pancreatic diseases. In 40 patients devoid of any disease of the gastrointestinal tract, the enzyme levels in the lymph were always higher than those in the blood serum. The results from the admin. of secretin, alone or with morphine or pancreozymin, or pancreozymin alone indicated that pancreatic stimulation alone does not cause any significant change in the thoracic duct lymph flow. Although all

EXOCRINE PANCREAS

min. substances caused some increase in the lymph enzyme levels, only after secretin and morphine or secretin and pancreozymin did the levels exceed the upper limit of the normal range.

Pancreatitis

LONG TERM OBSERVATIONS ON PATIENTS SUFFERING FROM ACUTE PANCREATITIS.

(Rus.) Shelagurov, A. A. (Pirogov Inst. Med., Moscow). Klin. Med. (Moskva) 44(2):51-57, 1966.

111 patients (85 women and 26 men; age 10-80 yr.) subjected to surgery for various pancreatic diseases and followed for periods ranging from 6 mo.-10 yr. In the onset of disease, recurrence was observed 1-6 yr. after treatment (mainly during the first and second yr.) in 80 patients. According to the type of pancreatic disease, recurrence was observed in 16 of 19 patients treated for acute hemorrhagic pancreatic necrosis, 5 of 8 subjected to cholecystectomy for acute cholecystopancreatitis, and 59 of 84 treated conservatively for acute edema of the pancreas. Recurrence was seen in 31 of 111 patients, namely 3 of 19, 3 of 8, and 25 of 84, all of the types described above. Blood diastase and lipase levels of patients in remission were normal or lowered; pancreatic enzyme conc. of duodenal juice was increased in some patients; blood sugar was increased in 9; 20 had pathological blood sugar curves. Thus, in the majority of patients, acute pancreatitis was transformed to recurrent chronic pancreatitis with periodic severe exacerbations and marked functional disturbances of the pancreas. In 11 patients, acute pancreatitis which developed during pregnancy or in early postpartum was also transformed into severe recurrent chronic pancreatitis. Detailed case histories are included. It is the author's opinion that patients with acute pancreatitis should be given extensive pancreatic enzyme therapy, should be hospitalized for longer periods, and should be under observation of a surgeon or clinician.

CHRONIC PANCREATITIS OF UNKNOWN ORIGIN. SURGICAL TREATMENT. (Sp.)

Campuzano, M. F. Gac. Med. Mex. 46(2):253-257, 1966.

73 patients subjected to surgery for recurrent pancreatitis, 28 were considered secondary to biliary disease, 23 of alcoholic origin, and 22 idiopathic. In 2 patients with the idiopathic form, no macroscopic pathology was seen at laparotomy, abnormal findings at pancreatography. However, the other 20 patients presented the following at surgery: fibrosis of the sphincter of Oddi (10); pseudocysts (6); biliary stenosis (5); pancreatic lithiasis (3); acinar carcinoma (1); insular carcinoma (1); papilloma of the papilla of Vater (1); pancreatic abscess (1). Results of surgical treatment by sphincterotomy alone were excellent in 9 of 11 (82%) patients. Among 11 patients treated by surgery other than sphincterotomy (12 operations), results were good to excellent in 8, while 3 died (1 abscess and 2 carcinomas of the pancreas).

MORPHOLOGY OF EXPERIMENTAL ACUTE PANCREATITIS. ITS VARIOUS PHASES. IN

DOGS. (Rus.) Toskin, K. D. and L. B. Rozinsky. Ark. Pat. 28(1):68-70, 1966.

Technic is described for the induction of acute pancreatitis in dogs. Following pancreatic resection and gastroenterostomy, the duodenal stump was exteriorized and an anastomosis created. Upon obstruction of the duodenal loop incorporated in the flap, 1-30 hr., various stages of acute pancreatitis were provoked in 10 dogs. In the early stages, changes occurred in the interlobular connective tissue and included hyperemia, swelling and disintegration of collagenous fibers, and development of serous, followed by purulent, inflammation of interstitial tissue. Later changes involved the parenchyma and consisted of necrobiotic changes followed by necrosis of the acinar cells. Despite the fact that RBC diapedesis and perivascular hemorrhage were observed in the early stages of acute pancreatitis, the massive hemorrhage of the later stages is a consequence of progressive necrosis of the parenchyma.

PATHOPHYSIOLOGIC ALTERATIONS IN EXPERIMENTAL PANCREATITIS. (E.) Carey,

L. C. and R. E. Rodgers. Surgery 60(1):171-178, 1966.

Pathophysiological changes were investigated in 31 splenectomized mongrel dogs in which pancreatitis was induced by infusion into the cannulated greater pancreatic duct of 20 ml of a buffered bile salt soln. containing active trypsin (Group 1; 10 dogs); by hand inj. of 10 ml of autogenous bile into the greater pancreatic duct (Group 2; 9 dogs); 11 animals served as controls. Ligation of the lesser pancreatic

duct, duodenotomy, and cannulation of the greater pancreatic duct were performed on all dogs; controls underwent sham manipulation. At 4 hr., animals of Group 1 had a greater plasma loss (mean plasma vol. deficit = 262 ml, or 34%) than those of Group 2 (21%). Plasma vol. changes in the latter group did not differ significantly from those of controls (14%). Peritoneal fluid vol. at 4 hr. was 155 ml for Group 1, 60 ml for Group 2, and 44 ml for controls. No increased trypsin activity was found in the plasma or peritoneal fluid of dogs of Group 1. No change in central venous pressure occurred between different groups or at various times in the same group. Mean arterial blood pressure fall was 44 mm Hg for Group 1, 27 mm Hg for Group 2, and 8 mm Hg for controls. Hepatic artery and superior mesenteric artery flows decreased progressively in all animals over the 4-hr. study period. Peripheral resistance was higher in hepatic and mesenteric vascular beds in all groups at 4 hr. than at 0 time, but differences between groups were not significant. Inj. of bile in Group 2 caused an immediate, transient fall in hepatic vascular resistance. No evidence was found suggesting the presence of vasoactive polypeptides. Results indicate the possibility that bile reacts with something in the pancreas which releases a potent vasodilator. If this is so, the substance seems to be altered in passage through the liver. The effect began with inj. and was gone in 5 min. It did not occur in the mesenteric or somatic vascular beds.

- 9191 SURGICAL TREATMENT OF CHRONIC, PRIMARY PANCREATITIS. LONG-TERM RESULTS AND PRESENT TRENDS IN TREATMENT, AS SEEN IN 100 OPERATED PATIENTS. (Fr. Moreaux, J. (Bichat Hosp., Paris), R. Pernod and J. Hepp. *Ann. Chir.* 20(5-6):438-446, 1966.

A review of current trends in the treatment of pancreatitis is supplemented by a report of the outcomes of treatment in patients undergoing a wide variety of surgical interventions for chronic, primary pancreatitis; 45 of 100 were lost to follow-up. Among 55 who could be located 2-10 yr. (median interval, 5) after surgery, 13 deaths and 27 favorable, 5 questionable and 10 unfavorable outcomes were reported. Causes of death were determined in 9 of 13. They included 1 death due to hepatic necrosis resulting from accidental ligation of the hepatic artery during surgery; 6 due to subsequent, acute pancreatitis accompanied by malnutrition, intractable pain, diabetes and toxicomania; 2 due to non-related causes. Surgical procedures in the 27 patients who reported favorable outcomes had included 6 anastomotic canalizations, 5 partial pancreatectomies (1 with sphincterotomy), 7 removals of cysts (no details except that 2 of 7 were accompanied by biliary anastomoses), 6 cases of unspecified biliary surgery and 2 cases of splanchnic neurectomy. One patient was not accounted for.

- 9192 ELECTROCARDIOGRAPHIC CHANGES DURING PAINFUL CRISES IN PANCREATITIS. (Fr. Lambert, H. (U. Geneva, Switzerland). *Cardiologia (Basel)* 48(4):387-390, 1966.

Among 50 patients with acute pancreatitis or recurrent pancreatitis in a state of painful crisis, significant electrocardiographic changes were seen in only 14 cases. Eleven showed typical flattening of the T-waves, with (4) or without (7) accompanying hypokalemia. In 1 case each, there were changes of the QRS complex and the terminal phase; auricular fibrillation; and suggestions of a myocardial infarct. These suggestions were not confirmed at autopsy of the patient, who was suffering from peripancreatic steatonecrosis and hepatic steatosis.

- 9193 REPORT OF HISTOPATHOLOGICAL FINDINGS IN EXPERIMENTAL PANCREATITIS IN THE RAT AND OF FINDINGS CONCERNING THE ORIGIN OF PANCREATIC PSEUDODUCTULI. (Ger.) Raso, P. (U. Minas Gerais, Belo Horizonte, Brazil), R. Dani, P. Godoy and R. C. Guimarães. *Zschr. Gastroent.* 4(2):96-100, 1966.

Experimental pancreatitis was induced in rats by admin. of trypsin in sodium malonate inj. just below the pancreatic capsule. Histologic changes were most marked in the exocrine secretory tissues, including parenchymal atrophy and replacement of entire lobules or portions thereof by fatty tissue or pseudoductuli, although pseudoductuli also appeared in circumscribed areas within lobules showing little other change. This was accompanied by the appearance of foci of degenerative changes in the acinar epithelium. The transformation of acinar cells into pseudoductuli appeared to take

e gradually and simultaneously, or nearly simultaneously, throughout the pancreas, usually involving a decrease of zymogen synthesis and clearly paralleling in extent degree of demonstrable destruction of the pancreatic parenchyma. There was no evidence of obstruction of the duct system or of individual ducts, except for possible transient blocking, due to edema, occurring in the very early stage of response to cation. There was little or no proliferation of connective tissue, appearing to be further confirmation of the involvement of a non-specific mechanism in formation of the pseudoductuli, similar to the ex-vacuo mechanism seen in bronchiectasis following destruction of the pulmonary parenchyma.

ACUTE AND CHRONIC PANCREATITIS: TRANSITION FORMS. (Fr.) Leger, L. (Cochin Hosp., Paris), A. M. Taschieri, G. Lemaigre and G. Bellanger. Arch. Ital. Chir. 91(5):493-516, 1965.

Authors present evidence of transition from acute to chronic pancreatitis in 12 patients (10 men and 2 women; age 25-49 yr.). In 7 patients, the severity of clinical manifestations prompted surgery during which diffuse or localized hemorrhagic areas were observed in 3, edema in 3, and cytosteatonecrosis in 5. No biliary tract lesions (except for gallbladder distention in 1) were observed. Wirsungography revealed permeable pancreatic duct in 3 patients and stenosis in 2; lithiasis was observed 3-10 yr. after the first hemorrhagic episode in 3. In another patient, transition occurred from acute necrotizing pancreatitis to chronic pancreatitis with lithiasis but without stenosis of the pancreatic duct or biliary tract lesions. In the remaining 4 patients, surgery revealed edema in all and cytosteatonecrosis in 2; permeability of the pancreatic duct was seen in at least 2 patients; biliary tract lesions were observed in 2; progression to lithiasis after 2 and 11 yr. was observed in 2 patients. The multiplicity of pancreatic response to various etiological factors is discussed.

TREATMENT OF PANCREATITIS BY LEFT SPLANCHNICECTOMY AND CELIAC GANGLIONECTOMY. ANALYSIS OF 146 CASES. (E.) White, T. T. (U. Washington, Seattle), M. Ławinski, G. Stacher, J. Pang Tay Tea, J. Michoulier, J. Murat and P. Mallet-Guy. Am. J. Surg. 112(2):195-199, 1966.

Splanchnicectomy proved to be effective treatment for recurrent pancreatitis when used for patients without stones in the pancreas or duct and without a dilated pancreatic duct. A 5-yr. follow-up on 116 patients showed that 68.9% presented good or excellent results and 83.6% obtained some benefit from a splanchnicectomy. Of the patients with chronic fibrotic pancreatitis (of whom many were alcoholics), 48.7% had few or no symptoms at the end of the 5 yr. Of the 44 patients who had gallstones as well as pancreatitis, and on whom a cholecystectomy as well as a splanchnicectomy was performed, 86.4% showed good or excellent results. In all, there were 8 deaths from pancreatitis and 30 operations were considered as failures. Besides the splanchnicectomy, the following were performed: 9 T-tube drainages of the common duct, 10 cholecystectomies, 4 gastrojejunostomies, 20 anastomoses of the bile duct to the intestine and 1 splenectomy.

LIVER AND BILIARY TRACT
GENERAL

- 2 HEPATIC CIRCULATORY AND FUNCTIONAL ALTERATIONS FOLLOWING SIDE-TO-SIDE PORTACAVAL SHUNT. (E.) Mulder, D. G. (U. California Sch. Med., Los Angeles), W. G. Plested III, W. N. Hanafée and J. F. Murray. Surgery 59(6):923-931, 1966.

Circulatory and functional tests were performed in 9 patients who had undergone side-to-side portacaval anastomosis for cirrhosis with portal hypertension and bleeding esophageal varices 6 mo.-7 yr. previously. Catheters were placed in the hepatic artery, hepatic vein, and the portal vein on the liver side of the shunt. Cineportography and hepatic arterial dye inj. demonstrated a retrograde blood flow (away from the liver) in the portal vein cephalad to the shunt in all cases. This retrograde flow seemed to have traversed the liver at the sinusoidal level and participated in hepatic metabolism in all 9 patients. Liver function tests showed that this altered circulation seemed clearly beneficial in 6 patients; it was of questionable value in 1, and in the other 2 it may have been detrimental. Balloon blockade of the portal vein cephalad to the shunt in 4 patients allowed comparison of the effects of an end-to-end and a side-to-side shunt in the same patient. There was no significant difference in liver function in any of these cases.

- 3 LDH ISOENZYMES IN CLINICAL PRACTICE. I. THERMOLABILE LDH FRACTION IN LIVER DISEASES. (Cz.) Kocián, J., J. Vaništa and M. Engliš. Cesk. Gastroent. Vyz. 20(2):91-95, 1966.

Values of the thermolabile fraction of serum lactic dehydrogenase (LDH₅ of the liver tissue) were determined in 19 patients with non-hepatic disease, and in 125 patients with liver disease (mild infectious hepatitis in 28 of 125, severe infectious hepatitis in 42 of 125, chronic hepatitis in 26 of 125, cirrhosis of liver in 14 of 125, and cancer of the liver in 15 of 125). It was concluded that elevation of this enzyme provides specific evidence of liver damage in 92.5%. Values above 10.0 %/ml or above 50% of the total activity of serum lactic dehydrogenase indicate severe liver damage, particularly a severe course of virus hepatitis.

- 14 IDIOPATHIC HEMOCHROMATOSIS. A STUDY OF THREE FAMILIES. (E.) Balcerzak, S. P. (U. Pittsburgh Sch. Med., Pa.), M. P. Westerman, R. E. Lee and A. P. Doyle. Am. J. Med. 40(6):857-873, 1966.

This study of three patients and their respective family members suggests that idiopathic hemochromatosis is an inherited iron storage disease which is initially recognizable by an abnormal iron absorption. However this symptom proved serviceable for diagnosis only if detected early because with time this increased iron absorption led to massive iron accumulation which, in turn, depressed absorption. Of the 27 family members examined, 13 had moderately to markedly increased iron stores (5 of these had hepatic cirrhosis). Iron absorption was measured in 22 of these 27 and was found to be normal in all those with an iron overload, but had increased in 4 of 13 family members with normal iron stores. In total, evidence of disorder of iron metabolism was found in 3 generations in 2 families and in 2 generations in the remaining family. Increased iron absorption was always detected in the third (young) generation. Consequently, the demonstration of iron excess in family members who are not anemic or alcoholic probably represents the most certain way at present of separating patients with idiopathic hemochromatosis from those with other iron-loading diseases.

- 15 ULTRASOUND STUDIES IN DIFFUSE LIVER DISEASES. (Ger.) Schentke, K. U. (Charité Hosp., Berlin) and F. Renger. Deutsch. Gesundh. 21(22):1013-1018, 1966.

One-dimensional pulse echo procedure (utilizing a 2.0 milliherz oscillator, 25 mm ch 650 impulse per second of 2.0 microsecond duration) was used to visualize the B-picture of 182 patients (40 normals; 22 minor interstitial hepatitis; 44 acute and 26 chronic hepatitis; and 50 with hepatic cirrhosis). The interval between inlet and outlet echos is almost smooth, in the control group containing only an av. of 3 intermediary echos with an av. amplitude of 6.0 mm (± 0.6). The av. number of intermediary echos in the 22 mild cases was 3.1 (± 0.4) with 7.3 (± 1.3) amplitude.

For the acute and chronic hepatitis groups, resp., the values were 5.5 (± 0.4) for both with resp. amplitudes of 12.9 (± 1.1) and 14.5 (± 1.5), while the cirrhotic group of 50 patients had an av. of 8.4 (± 0.3) intermediary echos, with av. amplitude of 34.2 mm (± 2.0). There were significant differences between the groups of normal or minor disease, acute or chronic hepatitis, and cirrhosis. The av. age of the groups (differences in connective tissue content of the liver) does not account for the results, since another group of 55 patients (cancer, without liver involvement, av. age 62, compared with 54 yr. for the cirrhotic group) had only 4.4 intermediary echos with av. amplitudes of 9.8. The resp. echograms were characteristic only in about 50% of the cases. Prolonged exposure (up to 24 hr. to above instrument -0.1 W/cm^2) did not adversely affect liver enzyme levels.

- 9216 COMPARATIVE STUDIES OF SOLUBLE PROTEINS FROM EMBRYONIC LIVERS, NORMAL LIVERS OF ADULT ANIMALS AND TRANSPLANTABLE RAT TUMORS, USING AGAR AND PAPER ELECTROPHORESIS. (Ger.) Fritz, W. (Potsdam/Rehbrücke Exp. Oncol. Inst., Germany). Zschr. Naturforsch. (B) 21(5):482-487, 1966.

Electrophoretic studies of homogenates of embryonic rat liver, those of normal adult rats and those of rats bearing hepatomas or i.m. inoculated Jensen or Yoshida sarcomas, Guerin carcinomas or Shay chloromas, showed characteristic differences for each of the groups and sub-groups. These were sufficiently marked to permit differential diagnosis between specific tumor types. In the absence of hepatic metastasis, qualitative differences were not demonstrable between liver homogenates from tumor-bearing and control animals, but quantitative differences included an increase of α -globulin by 6-8%, a decrease of β_1 -fraction by 3-6% and a decrease of γ -fraction by 3-5%. In the presence of Paris ascitic hepatoma, the post- γ -globulin fraction was increased by approx. 7%. It is concluded that histologic diagnosis of biopsy specimens in man should be complemented by electrophoretic characterization of the same specimens, using agar or acetylcellulose.

- 9217 LIPID METABOLISM IN FATTY LIVER OF LYSINE- AND THREONINE-DEFICIENT RATS. (E.) Viviani, R. (U. Bologna Sch. Vet. Med., Italy), A. M. Sechi and G. Lenaz. J. Lipid Res. 7(4):473-478, 1966.

Multiple metabolic defects resulted in rats fed on a low protein diet which was deficient in lysine and threonine. Liver lipids contained less amino phospholipids and more lecithin, sphingomyelin and free fatty acids than normally. No variation on fatty acid composition of choline- and ethanolamine-containing phospholipids was found and the only serine-containing phospholipid which increased was palmitic acid. The incorporation of acetate- C^{14} into phospholipids (but not other liver lipids) was lower in these deficient rats. Also, their plasma conc. of esterified fatty acids and phospholipids was lower, while the free fatty acid conc. were higher.

- 9218 IMMUNOCHEMICAL OBSERVATIONS IN CLINICAL HETEROLOGOUS (XENOGENEIC) LIVER PERFUSIONS. (E.) Norman, J. C. (Harvard Med. Sch., Boston, Mass.), C. A. Saravis, M. E. Brown and W. V. McDermott, Jr. Surgery 60(1):179-190, 1966.

Developmental methods in initial porcine liver perfusions are described. Serial perfusions were carried out on 5 patients entering end-stage hepatic failure, the longest period of observation being 18 days after the first of 5 perfusions. Among the immunochemical techniques used to analyze the "ascites" and bile produced by the ex vivo porcine liver preparation and serial aliquots of the patients' sera before, during, and after perfusions were: (1) microzone electrophoresis; (2) qualitative and quantitative immunoprecipitation reactions between patients' sera and fresh porcine serum in serial dilutions to detect the presence of patient antibody nitroto porcine antigen; (3) tanned-cell hemagglutination techniques for detection of patient antibody; (4) immunoelectrophoresis on cellular acetate and (5) immuno-diffusion studies, both using monospecific antihuman or antiporcine sera. The "ascitic fluid" was found to be an ultrafiltrate of the patients' plasma (1, 4, 5), containing only trace amounts of porcine proteins (4, 5). Bile analyses (4, 5) indicate that the protein content is all human in origin; moreover, bilirubin conc. in the "ascitic fluid" is 3-4 times that simultaneously occurring in the patient's serum. Immunochemical analyses of patients' sera indicate deficiencies of α -, β -, and γ -globulins.

cluding 19S gamma globulin (immunoglobulin M); however, the presence of 7S γ -globulin (immunoglobulin G) has been noted prior to perfusion, indicating potential antibody formation capability (1, 4). Improvements in γ - and β -globulins following perfusion could not be attributed to porcine liver perfusion per se because whole blood and fresh frozen plasma were admin. to the patients during perfusion. The presence of porcine proteins in patients' sera prior to perfusion, their presence following perfusion, and their increase following each serial perfusion was demonstrated (5). Despite the presence of these porcine potential antigens, no demonstrable antibody response in the patients was found (2, 3, 5). Possible explanations for this lack of antibody response are presented.

19 LIVER FUNCTION AFTER MYOCARDIAL INFARCTION. (E.) Aber, C. P. (United Liverpool Hosp., England), P. E. Brunt, E. W. Jones, T. G. Richards, A. H. Short and V. Bernstein. Lancet 1(7452):1391-1393, 1966.

Serum lactic dehydrogenase (I) isoenzyme patterns and sulfobromophthalein (II) excretion were monitored in 10 patients surviving recent myocardial infarction. Initial I and II studies were made within the first 24 hr. after admission to the hospital; subsequent I observations were on post-vital days 2, 4, 6 and 8, and then at 3-4-day intervals until a normal distribution pattern was observed, at which time a repeat II test was made in patients with an abnormal initial test. Actuation of activity of I bands was present in all patients within 12-24 hr. after the infarct. Seven patients also showed some abnormality in the II test. The worse the clinical distress of the patients, the more striking were the abnormalities in both measurements. Some patients had excessive retention of II at a time I patterns had returned to normal one mo. or more after the infarction. The results are interpreted as supporting the view that increased I activity following myocardial infarction originates from the liver, and that impaired liver function frequently occurs in these patients.

20 PROGNOSIS IN ACUTE LIVER DISEASE OF THE ALCOHOLIC PATIENT. (E.) Hardison, W. G. (Thorndike Mem. Lab., Boston, Mass.) and F. I. Lee. New Eng. J. Med. 275(2):61-73, 1966.

The clinical records of 87 hospital admissions (53 male, 34 female) with clinically diagnosed severe acute liver disease and recent history of excessive alcohol ingestion were reviewed in an attempt to discover factors appearing early in the hospital course that might correlate with a poor prognosis. Excluded from the study were patients admitted because of gastrointestinal hemorrhage, sepsis, or heart failure; those with known biliary tract disease; those discharged in less than 10 days; and those whose serum bilirubin never exceeded 1.9 mg/100 ml. Data from the patient's history, physical findings on admission, and laboratory tests were recorded and statistically analyzed with respect to mortality. Overall mortality was 78%. The presence of asterixis was the only physical finding on admission associated with a statistically significant increase in mortality. Higher mortality rates were significantly associated with higher mean values of only 3 of the admission laboratory tests: the white blood cell count, serum bilirubin, and serum urea nitrogen. Data obtained during the hospital course could not be analyzed statistically, but admission serum bilirubin over 5 mg/100 ml that did not begin to fall by day 6 after admission was associated with a poor prognosis (78% mortality). Increased mortality was not significantly associated with age, sex, history of previous admission, presence and degree of hepatomegaly, or high values of serum glutamic-oxalacetic transaminase, or serum alkaline phosphatase.

21 AUXILIARY LIVER TRANSPLANTATION: EFFECT OF HOST PORTACAVAL SHUNT. EXPERIMENTAL AND CLINICAL OBSERVATIONS. (E.) Halgrimson, C. G. (U. Colorado Sch. Med., Denver), T. L. Marchioro, T. D. Faris, K. A. Porter, G. N. Peters and T. E. Starzl. Arch. Surg. (Chicago) 93(1):107-118, 1966.

Experimental observations of auxiliary liver transplants in 11 dogs indicate that the portacaval shunt does have some protective effect upon the homograft, but does not prevent the atrophic process from occurring. In 8 dogs the homograft received both an hepatic arterial inflow as well as a portal supply with venous blood; in the other three, only an arterial supply existed. Transplant atrophy was partially

LIVER AND BILIARY TRACT

prevented when the homograft had a double blood supply; it was not influenced when both the homograft and the host liver each had only an arterial supply. In all cases moderate atrophy was observed in autologous livers, indicating that the protective effect was at least partly at the expense of injury to host hepatic tissue. Using operations designed to provide homografts with a physiologic advantage, three attempts at clinical auxiliary transplantation were made. In 2 adult patients who eventually died of sepsis there was evidence of homograft function. The third attempt in a child resulted in technical failure. The deficiencies of auxiliary transplantation techniques are discussed.

- 9222 THE LIVER IN GENERALIZED GLYCOGEN STORAGE DISEASE. LIGHT MICROSCOPIC OBSERVATIONS. (E.) McAdams, A. J. (Child. Hosp., Cincinnati, Ohio) and H. E. Wilson. Am. J. Path. 49(1):99-111, 1966.

Liver specimens from 4 patients with Type II glycogenolysis were subjected to a variety of fixing, embedding, and staining methods and examined under the light microscope. The most significant alteration was the presence in hematoxylin and eosin sections of many relatively uniform 1-2-micron non-lipid vacuoles, which are dispersed throughout the cytoplasm. Timed sequences, over periods of 15 seconds to 30 min., of the effect of malt diastase digestion on periodic acid-Schiff (PAS)-stained specimens were made. In formalin-fixed, paraffin-embedded tissue, glycogen could not be demonstrated in the vacuoles, which remained PAS-negative; but in glutaraldehyde-fixed, Epon-embedded tissue it appears as dense PAS-positive bodies surrounded by cytoplasmic glycogen granules. Because a longer period for glycogen digestion is required with Epon-embedded specimens (attributed to the non-wettable nature of the plastic), the use of thin sections (0.5- and 1.0-micron) and interruptions at 15-second intervals demonstrated that the glycogen in the dense bodies is more susceptible to digestion (complete at 90 seconds) than is the generally distributed cytoplasmic glycogen (complete at 10 min.). It is suggested that the largely monoparticulate nature of glycogen in the dense bodies accounts for its greater diastase susceptibility, and that great solubility of monoparticulate glycogen accounts for the failure to demonstrate it in the vacuoles in aqueous (formalin-fixed tissue).

- 9223 A STUDY OF THE EEG IN LIVER DISEASES, WITH SPECIAL REFERENCE TO THEIR PROTEIN METABOLISM. (Cz.) Vojtěchovský, M. (U. Prague, Czech.) and J. Horký. Cesk. Neurol. 29(3):169-176, 1966.

In 3 years' observation of 53 patients hospitalized for liver disease, only 15% were found to have markedly abnormal electroencephalogram (EEG) (all were patients in the early stages of clinically manifest portal-system encephalopathy). Of the patients with decompensated or active cirrhosis of the liver, only 30% had EEG changes. In the majority of the patients with compensated and stabilized cirrhosis as well as those with chronic hepatitis, the EEG findings were comparable to those in the overall population. Changes in the EEG were not consistently correlated with the clinical course, although they reflected it more accurately than the ordinary neurologic examination. In individual patients, normalization of the EEG picture was observed after such therapeutic measures as the oral admin. of 5-hydroxytryptophan, the anabolic steroid hormone preparation Durabolin, and the antibiotic aureomycin, and after dietary protein restriction. Experience with the EEG activation method in 13 patients, most of them with compensated cirrhosis of the liver and normal EEG findings, suggested that this test has little discriminatory value. Neither a test breakfast of 100 g protein nor oral admin. of 5 g ammonium chloride produced conspicuous or characteristic EEG changes, as compared with those occurring in healthy controls.

- 9224 EXPERIMENTAL ASCITES. VII. THE EFFECTS OF EXTERNAL DRAINAGE OF THE THORACIC DUCT ON ASCITES AND HEPATIC HEMODYNAMICS. (E.) Orloff, M. J. (U. California Sch. Med., Los Angeles), P. W. Wright, M. J. DeBenedetti, N. A. Halasz, D. L. Annetts, M. E. Musicant and B. Goodhead. Arch. Surg. (Chicago) 93(1):119-130, 1966.

Effects of external drainage of the thoracic duct through a fistula in normal dogs and in dogs with congestive cirrhosis, portal hypertension, and massive ascites

ER AND BILIARY TRACT

duced by ligation of the hepatic vein are presented. No acute or chronic effects on portal pressure, vena caval pressure, thoracic duct pressure, or lymph flow rate were observed in 15 normal animals. In 17 animals with congestive cirrhosis, portal hypertension, and massive ascites, the thoracic duct was dilated, the lymph hemorrhagic, the lymph flow rate $5\frac{1}{2}$ times normal, and thoracic duct pressure greater than twice normal. A chronic thoracic duct fistula produced a 28% reduction in thoracic duct pressure, but did not overcome lymphatic hypertension nor alter portal blood flow. The animals that received incomplete replacement of lymph showed a reduction in central venous pressure and blood volume; whereas, those receiving complete replacement showed a slight increase in both parameters. The former group oliguria developed, blood urea nitrogen increased, and ascites increased; whereas, in the latter group the thoracic duct fistula had no influence on ascites or urine output. In all cases chronic thoracic duct drainage produced an increase in both lymph and serum protein. External drainage of the thoracic duct is an inefficient and hazardous way to decompress an obstructed vascular liver bed and does not overcome portal hypertension since relief of ascites via this technic appears to be due to removal of protein-rich fluid from the body.

- 5 PERFUSION DYNAMICS FOR EXTRACORPOREAL HEPATIC ASSIST. (E.) Tait, I. B. (U. Kentucky Med. Sch., Lexington) and B. Eiseman. Arch. Surg. (Chicago) 93(1):131-141, 1966.

A combination of perfusion dynamics providing optimal liver function during clinical extracorporeal hepatic assistance was studied. Temperatures above and below 38°C depress liver function. Perfusion through the portal vein of 500 ml/min. to a 1-kg liver supported optimal function, whereas, lesser flows resulted in specific functional deterioration in proportion to depression in flow. At flows below 500 ml/min. through the portal vein and hepatic artery in parallel, liver function diminished just as it did with perfusion solely of the portal vein. Flows greater than 500 ml/min. did not improve liver function appreciably. Bile production remained better than with perfusion solely through the portal vein. This circuitry combined benefits of both single vessel perfusions. Imposing a pulse pattern on portal venous perfusate flow did not alter liver formation; only ammonia clearance improved. Bile production was enhanced by a pulse pattern on hepatic artery perfusate, especially at a flow of 300 ml/min. Pulsating both hepatic artery and portal vein perfusates at 300 ml/min. and 400 ml/min. showed a significant increase in bile production. It appears advantageous to use pulsatile perfusion in clinical extracorporeal assist on hepatic artery alone or in parallel with portal vein.

- 26 HEPATOLENTICULAR DEGENERATION: THE COMPARATIVE EFFECTIVENESS OF D-PENICILLAMINE, POTASSIUM SULFIDE, AND DIETHYLDITHIOCARBAMATE AS DECOPPERING AGENTS. (E.) Hsia, Y. E. (Yale U. Sch. Med., New Haven, Conn.), J. T. Combs, L. Hook and I. K. Brandt. J. Pediat. 68(6):921-926, 1966.

Copper balance studies were performed in 3 patients (age 10, not specified, and 15 years) with hepatolenticular degeneration on a low copper diet and under treatment with potassium disulfide, D-penicillamine, and diethyldithiocarbamate. Copper was determined by a modification of the oxalyldihydrazide method of Rice and Grogan. D-penicillamine induced a marked cupriuresis roughly proportional to the dose given. Diethyldithiocarbamate did not produce a cupriuresis. Upon combination of these two drugs, the effect was no greater than when D-penicillamine was used alone. Although potassium sulfide was moderately effective in increasing copper stool excretion, the patient continued to have positive copper balance and had only a slight net loss. D-penicillamine remains the drug of choice for long-term decoppering therapy.

- 27 RECURRENT CHOLESTATIC JAUNDICE OF PREGNANCY. REPORT OF FIVE CASES AND ELECTRON MICROSCOPIC OBSERVATIONS. (E.) Eliakim, M. (Hadassah U. Hosp., Jerusalem, Israel), E. Sadovsky, O. Stein and Y. G. Shenkar. Arch. Intern. Med. (Chicago) 117(5):696-705, 1966.

Fourteen episodes of recurrent cholestatic jaundice of pregnancy occurred in 5 women of Oriental extraction wherein the clinical symptoms of either pruritus or jaundice (or both) disappeared shortly after delivery. The nature of the delivery was unrelated as, in one case, the disease persisted 42 days after an intrauterine fetal

death. Fever and hepatosplenomegaly were absent. The increases seen in urobilinogen excretion, serum alkaline phosphatase and total cholesterol persisted somewhat longer after delivery than the clinical symptoms, but they also returned to normal. In one patient, pruritus disappeared 24 hrs. after the initiation of corticotropin i.v. and remained absent with triamcinolone (4 mg/day) treatment, only to recur when this treatment was stopped. Electron microscopy of the liver in one patient revealed dilatation of the bile capillaries as well as flattening and distortion of the microvilli. The resemblance of recurrent jaundice of pregnancy to 17-alkyl steroid liver disease is significant.

- 9228 BIOPTIC AND BIOCHEMICAL STUDIES OF THE LIVER IN RHEUMATOID ARTHRITIS AND IN ANKYLOSING SPONDYLITIS. (Pol.) Kokot, F. (3rd Clin. Intern. Med., Katowice, Poland), A. Nowak, T. Zieliński, J. Zmudzinski, H. Grzybek and J. Aleksandrowicz. Pol. Arch. Med. Wewn. 36(3):339-344, 1966.

Histologic and histoenzymatic studies (the latter with reference to γ -glutamyl-tripeptidase) of liver sections obtained by biopsy, as well as a series of biochemical studies (of serum enzymes and proteins) generally used in hepatologic diagnosis were carried out in 33 patients with chronic, progressive, rheumatoid arthritis and in 10 patients with ankylosing spondylitis. It is concluded that the rheumatoid processes in the liver involve mainly the mesenchymal hepatic elements (in 66% of cases) and only rarely involve the hepatic cells themselves.

- 9229 ACTIVE COPPER TRANSPORT IN MAMMALIAN TISSUES--A POSSIBLE ROLE IN WILSON'S DISEASE. (E.) Neumann, P. Z. (Montreal Child. Hosp., Canada) and M. Silverberg. Nature (London) 210(5034):414-416, 1966.

Copper⁶⁴ acetate was accumulated against a conc. gradient by slices of rat liver and kidney cortex and by Ehrlich mouse ascites cancer cells. This accumulation was enhanced by the presence of histidine. The uptake of Cu⁶⁴ was significantly reduced at 20°C and was abolished in an anaerobic atmosphere. When maximal uptake was reached after 3 hr. incubation, the conc. of histidine, rather than that of copper, seemed to be the limiting factor. The subcellular distribution of Cu⁶⁴ was as follows: microsomes, 38%, mitochondria, 25% and supernatant, 6%. These data indicate that an intracellular active transport system for copper is present which is linked with amino acids, particularly histidine.

- 9230 PLASMA PHOSPHOLIPIDS IN PATIENTS WITH LIVER DISEASE. A QUANTITATIVE THIN LAYER CHROMATOGRAPHIC STUDY. (E.) Gjone, E. (U. Oslo Roy. Hosp., Norway) and O. M. Orning. Scand. J. Clin. Lab. Invest. 18(2):209-216, 1966.

Thin layer chromatographic studies (silica gel G) of plasma phospholipids showed a decrease in the absolute and relative lysolecithin values in cases of chronic parenchymatous liver disease. The levels were lowest in the severest cases of liver damage. Analyses were made on plasma collected after overnight fasting from 4 cases of acute hepatitis, 8 cases of liver cirrhosis and 8 of obstructive jaundice. Except for the obstructive jaundice cases, the relative amounts of cephalin, lecithin and sphingomyelin were within the normal ranges (4.6%, 72.8% and 17.3%, resp.). With obstructive jaundice, the low lysolecithin levels were accompanied by a marked increase in lecithin. These findings indicate that a dual mechanism controls plasma lysolecithin levels: the degree of liver damage, and acylation (which seems to increase with conditions giving rise to an increased free fatty acid plasma level).

- 9231 LATEX FIXATION TESTS IN LIVER DISEASES. (E.) Chew Beng Keng and K. L. Yeo. Singapore Med. J. 7(1):38-41, 1966.

Of 100 cases with various types of liver disease, only those with extra-hepatic obstructive jaundice (10 cases) or with hepatic amebiasis (11 cases) were 100% negative to the latex fixation test (Hyland RA test). The following cases showed a positive test: 17 of 39 with cirrhosis of the liver, 6 of 10 with primary carcinoma of the liver and 8 of 24 with infectious hepatitis. All of the 8 miscellaneous cases (Steven-Johnson Syndrome, glucose-6-phosphate dehydrogenase deficiency, leptospirosis and hemochromatosis) gave negative results. The conclusion is reached that where either hepatic amebiasis or extra-hepatic obstructive jaundice is suspected, a negative latex fixation test would support this diagnosis.

UR AND BILIARY TRACT

2 EFFECT OF ACID-BASE CHANGES ON RENAL CLEARANCE OF BILE PIGMENTS. (E.)

Ali, M. A. M. (Royal Free Hosp., London) and B. H. Billing. Clin. Sci. 30(3):543-552, 1966.

The effect of acid-base changes on the renal clearance of conjugated bilirubin was investigated in 33 male Sprague-Dawley rats with ligated bile ducts and under mannitol diuresis. Infusions of ammonium chloride (0.94 millimoles/hr.) or sodium bicarbonate (78 millimoles/hr.) for 6 hr. caused a decrease (72-88% of initial value) and increase (25-60% of initial value), resp., in bilirubin clearance; when both were given, the decrease following ammonium chloride was reversed by sodium bicarbonate. Acetazolamide (Diamox; 7.5 mg/hr.) decreased the value of bilirubin clearance, and the clearance ratio was related to the blood pH and was independent of the urine pH. In 3 patients with obstructive jaundice due to cholestatic hepatitis, carcinoma of the head of the pancreas, and carcinoma of the bile duct, no appreciable change in the pigment excretion was observed when urine vol. increased from 0.45 to 13.7 ml/min. under water diuresis. Increased bilirubin clearance and a rise in blood and urine occurred after the admin. of sodium bicarbonate. An oral dose of ammonium chloride caused a mean reduction in blood and urine pH of 0.05 and 0.45, resp., and a reduction in bilirubin clearance of 20-53% of the initial value. In vitro it was shown that the plasma protein binding capacity for conjugated bilirubin decreased with alkalosis and increased in acidosis.

33 TREATMENT OF HEPATIC COMA WITH ORNITHINE ALPHA-KETOGLUTARATE. (Fr.)

Tête, R., P. Paliard and A. Vachon. Rev. Lyon. Med. 15(8):371-378, 1966. Effects of i.v. perfusion of ornithine α -ketoglutarate (10-25 g/day; 50 g/day in 1 case) were studied in 17 patients (10 men and 7 women; age 29-70 yr.) with neuro-psychiatric manifestations due to alcoholic cirrhosis (10), Banti's disease (1), cirrhosis (1), cancer and cirrhosis (1), jaundice and alcoholic liver (1), or portacaval shunt for cirrhosis (3). Among the 11 patients with cirrhosis or Banti's disease, 7 had coma, of whom 2 responded to treatment, 2 showed improvement but died later from impaired liver function, and 3 showed transient improvement but died later in terminal coma; 2 patients with pre-coma responded to treatment; 2 patients with cephalopathy following portacaval shunt responded to treatment. A patient with cirrhosis and pre-coma was successfully treated. In the patient with cancer and cirrhosis, post-hemorrhagic coma responded to treatment, but the patient died later in terminal coma. In the patient with infectious jaundice and alcoholic liver, coma regressed after treatment, but the patient died from renal insufficiency. Of 3 patients subjected to portacaval shunt for cirrhosis, coma regressed in 1, failed to appear in 1 due to preventive admin. of the agent, regressed temporarily in the other, and then died from intercurrent complications.

34 MANAGEMENT OF PORTAL HYPERTENSION SECONDARY TO BILE DUCT STRICTURES:

REVIEW OF 18 CASES WITH SPLENORENAL SHUNT. (E.) Sedgwick, C. E. (Lahey Clin. Found., Boston, Mass.), J. K. Poulantzas and G. A. Kune. Ann. Surg. 163(6):949-953, 1966.

Splenectomy and splenorenal shunt were employed to treat 18 patients with biliary cirrhosis and severe portal hypertension resulting from prolonged obstruction of the bile duct following cholecystectomy. All had suffered recurrent attacks of cholangitis, and hemorrhage from esophageal varices had occurred in 17 of 18. All have histories of prolonged neglect or unsuccessful attempts to repair the bile duct stricture. There was 1 operative death, due to thrombosing of the shunt. One patient died after subsequent bile duct repair, 2 died later of unrelated causes and 1 died of hepatic failure which was attributed to multicentric hepatomas in 1 case and to thrombosing of the shunt in 2 of the other 3. Among the 10 patients surviving 1-84 mo. at the time of report, 8 were entirely symptom-free, 1 had mild symptoms of portal systemic encephalopathy and 1 was experiencing recurrent attacks of cholangitis. It is concluded that external drainage of the common bile duct is indicated as a (sole) first procedure in patients with profuse hemorrhaging resulting from portal hypertension in the presence of a high degree of biliary obstruction, followed in 3-4 wk. by splenorenal (rather than portocaval) shunt and then by reconstruction of the bile duct after liver function has returned to an optimal level. In patients with potentially fatal hemorrhaging from esophageal varices, but lesser

degrees of bile duct stricture, external drainage of the bile duct to achieve biliary decompression may not be necessary as a prelude to construction of the shunt.

- 9235 OUR EXPERIENCE WITH ORTHOTOPIC AND HETEROTOPIC LIVER TRANSPLANTS IN DOGS. (Fr.) Mikaeloff, P. (Nat. Inst. Military Services and Res., Lyon, France), G. Dureau, J. P. Rassat, M. Dubernard, J. Belleville, P. Coeur, J. Malluret, J. Tronchon, J. Bomel, G. B. Richard and J. Descotes. *Rev. Medicochir. Mal. Foie* 41(2):51-74, 1966.
